SURGERY OF STENOTIC VALVULAR DISEASE OF THE HEART

ROBERT P. GLOVER, M D.
CHARLES P. BAILEY, M D.
and

Philadelphia

The past decade has seen the development of cardiac surgery assume a position of major importance, to climax a half century of far-reaching surgical achievement For the most part, however, this surgery has been cardiovascular in nature and has been directed at the great vessels in close proximity to the heart (patent ductus arteriosus, coarctation of the aorta and anomalies of the aortic arch). Even when the vascular defects lay within the confines of the cardiac chambers (tetralogy of Fallot or mitral stenosis), newly developed familiarity with vascular anastomoses and an inborn dread of violating the sanctity of the heart itself suggested that indirect relief by vascular shunts might offer the most reasonable and effective solution, The brilliant successes of Gross,[1] Crafoord and Nylin,[2] Blalock[3] and Sweet[4] have been epochal in this regard, and their contributions cannot be overestimated.

Concomitantly with these essentially extracardiac developments, however, Smithy,[5] Harken and others,[6] Brock,[7] Murray, Wilkinson and McKenzie,[8] we ourselves[9] and others have been concerned with the development of intracardiac procedures designed for the relief of valvular disease and have focused attention on the direct cardiac approach; in so doing we have reaffirmed the right of cardiac surgery as a definitive entity.

Lest one be tempted to suspect that the conception of cardiac surgery is of recent origin one has but to review the pioneer efforts of Rehn,[10] who successfully sutured a heart wound in 1897, Doyen[11] (1913), Tuffier[12] (1913), Allen and Graham[13] (1922), Souttar[14] (1925), Pribram[15] (1926), Cutler and Beck[16] (1929) and many others to appreciate that "true cardiac" surgery, initially handicapped by the immature state of surgical technic and anesthetic methods, nevertheless had its inception in the minds and actions of surgeons before many of us entertained the thought of embracing surgery as a specialty. Should valvular surgery of the heart in particular and intracardiac surgery in general become practical, and they have shown every indication of becoming just that, these men deserve a great measure of acclaim for their foresight; their contributions must not be forgotten in the enthusiasm of a presumably new and rapidly developing field

It is logical that valvular disease of the heart should be among the first of the intracardiac disorders to be subjected to surgical consideration. It is common and found universally. Although the effects of rheumatic disease on the mitral and aortic valves make the acquired variety by far the commonest of all valvular defects, congenital stenosis of the pulmonary valve and conus as it occurs in the tetralogy of Fallot has received the greater attention to date due primarily to the ingenious systemic-pulmonary shunt devised by Blalock and Taussig.[17] As is well known, such an extracardiac shunt essentially by-passes the intracardiac pulmonary obstruction, redirecting mixed venous-arterial aortic blood into the pulmonary vascular bed where its oxygenation effectively relieves the clinical

signs and symptoms manifested by the highly publicized "blue baby." Thus an additional (fifth) defect has been added to four already present in the tetralogy of Fallot, albeit one which in large measure overcomes the immediate and obvious effects of the condition under consideration. Nevertheless, a "patent ductus arteriosus" has been created, a defect which were it to be found in existence alone would demand early surgical correction. The late effects of such an arteriovenous fistula on the heart and circulation are well known, and although the interventricular septal defect in the tetralogy may conceivably counteract in some measure the deleterious late effects of an artificially produced ductus, there is certainly cause for real concern as to the eventual fate of a patient with such dangerous anomalies.

Without detracting in the least from the brilliant results achieved by the Blalock operation (subclavian artery–pulmonary artery anastomosis) or from its clever modification, the Potts operation[18] (direct aorta–pulmonary artery anastomosis), it would seem entirely reasonable to attempt direct relief of the pulmonary obstruction, thereby reducing (and not increasing) the number of defects with which the patient must contend. In order to effectively accomplish such an obviously desirable feat it is essential to thoroughly understand the nature of the obstruction in the pulmonary channel and to have perfected means of rapid, safe and efficient correction of this obstruction. Initial results of a direct surgical approach must be comparable to those already obtained by shunt procedures, and the prospect that the patient will have a more nearly permanent relief and a more certain future after undergoing operation by the direct method must at least theoretically outweigh present doubt which exists concerning the eventual physical havoc that may result from the presence of such a surgically-produced shunt.

CONGENITAL VALVULAR DISEASE

Pulmonary Stenosis.—Although a large number of cyanotic patients with various types of pulmonary obstruction have been studied clinically and treated surgically, there are few detailed data available as to the relative incidence of the individual anatomic variances which may be present within the right ventricular outflow tract or at the root of the pulmonary artery. It is well known, however, that pulmonary valvular stenosis may exist as a single defect or be found in association with any combination of intracardiac anomalies, particularly those designated by the term tetralogy of Fallot (pulmonary stenosis, overriding aorta, interventricular septal defect and hypertrophy of the right ventricle). To further complicate this picture the pulmonary stenosis component frequently may not be strictly valvular but rather infundibular, i. e., a muscular hypertrophy or fibrous malformation of the ventricular myocardium proximal to the pulmonary valve. As a result of this somewhat confused pathological pattern, it has been considered impractical to attempt definitive anatomic diagnosis of the type of pulmonary block but to be content with the compilation of functional or physiological data merely to confirm the presence of such an obstruction. Thus, for several years the demonstration of a greatly diminished pulmonary blood flow in a cyanotic child has called for the surgical production of a systemic-pulmonary shunt regardless of the type of obstruction.

Mindful of the aforementioned objections to the creation of such a shunt, Brock[7] devoted considerable energy to a study of the pulmonary artery-conus segment in cyanotic heart disease in the hope that clarification might lead to a direct and logical surgical approach. His findings and subsequent conclusions are brilliant examples of the basic role played by exacting pathological observation in the development of any new surgical procedure. He has described the following variations: (1) pure valvular stenosis; (2) a high degree of pulmonary artery hypoplasia with a bicuspid valve and stenosis lying immediately subvalvular in a narrow muscular channel; (3) a high infundibular stenosis proximal to a relatively normal pulmonary artery and valve (the commonest type), and (4) a low infundibular stenosis, at varying levels, creating a small or large infundibular chamber (third ventricle) proximal to a normal pulmonary artery and valve. The wall of this chamber may be either thin and fibrous or muscular in nature (fig. 1).

As a result of these observations, Brock[7] in 1948 reported a new type of operation for the relief of congenital pulmonary stenosis. It is true that Doyen had previously attempted direct division of what was thought to be a stenosed pulmonary valve in 1913, but nothing further developed from this original effort. Inasmuch as pulmonary stenosis may be valvular or infundibular, two procedures were devised:

1. For relief of valvular stenosis entry is made through the right ventricle 3 cm. proximal to the valve. A small probe is inserted through the incision and passed into the mouth of the pulmonary artery to gage the position and degree of stenosis. A specially designed, flat, cobra-shaped knife with sharp cutting edges converging into a small noncutting rounded tip is guided into the fused valve cone, engaged through the tiny pinhole orifice and gently thrust onward into the pulmonary artery (fig. 2 *B*). The valve is thus divided into two equal cusps, one anterior and one posterior, which can open and close in response to changes in systolic and diastolic ventricular pressures. The knife is removed, a dilating sound or one's little finger is introduced through the opened valve to insure adequate separation of the newly formed cusps.

2. Should direct observation and palpation of the right ventricle and pulmonary artery at the time of surgical intervention suggest the presence of an infundibular type of obstruction, an alternative procedure is used. The ventricular chamber is entered either proximal or distal to the obstructing septum, and by means of a backward-cutting punch a collar of tissue is excised; this greatly enlarges the diameter of the outflow channel, allowing the venous blood stream to pass normally through the adequate pulmonary valve, artery and bed (fig. 2 *A*). In either case the ventricular incision is closed by using three or four interrupted sutures of strong vascular silk.

By 1949 Brock[19] was able to report that five cases of congenital pulmonary stenosis had been successfully treated by using the foregoing technic. Since that time he has operated on a much larger number of patients, both in this country in collaboration with Blalock and in England, with excellent results.

In December 1949, after prolonged deliberation and because of considerable experience obtained during the development of mitral valve surgery, we followed the suggestions of Brock and embarked on a course of direct pulmonary attack for routine cases of tetralogy of Fallot. Eight operations have been performed to date. Much to our surprise, a valvular stenosis was present in four of the eight patients, a much higher incidence than has been presumed to occur in this combination of defects. The ages ranged from 3½ years to 18, the fused valve cones were divided with strict adherence to the technic outlined above without undue incident, and in each instance the preoperative cyanosis has disappeared. In three patients the improvement in exercise tolerance has been striking, and the fourth patient has shown decided improvement but the operation was too recent to permit more adequate evaluation. Preoperative compensatory polycythemia has disappeared, peripheral arterial oxygen saturations have been greatly elevated in those so examined, and the low, directly measured pressures within the pulmonary artery before valvular division have risen to within normal range at the termination of the procedure (table 1).

---

[18] Potts, W. J., and Gibson, S.: Aortic Pulmonary Anastomosis in Congenital Pulmonary Stenosis: Report of 45 Cases, J. A. M. A. **137**: 343 (May 22) 1948.

[19] Brock, R. C.: The Surgery of Pulmonary Stenosis, Brit. M. J. **2**: 399, 1949.

In the four remaining cases the stenosis was infundibular, of the type shown in figure 1 *C*. Although in each instance the high location of the stenosis was suspected, the incision in the myocardium was inadvertently made directly over the infundibular septum, making the use of the Brock backward-cutting punch impossible. In the first of these infundibular cases (case 5) the condition of the patient at this point was so critical that digital and instrumental dilatation to forcibly enlarge the channel was all that could rapidly be accomplished so that the procedure could be terminated. Although there was no reason to believe that the child would survive the operation after a stormy postoperative convalescence his improvement has been progressive, cyanosis has disappeared except with excessive exercise and the parents are delighted with the degree of normality which has been unexpectedly achieved. As a result of this experience, when the same problems were confronted in the ensuing three cases we were prepared with a small sharp bone rongeur with which a segment of septal tissue about 1.8 cm. (the size of a dime) was removed through the opening in the myocardium, an opening which extended vertically above and below the underlying septal ridge and at right angles to it (fig. 2 *C*). Each of these patients improved rapidly after operation. Cyanosis disappeared (immediately in one, within a few days in a second and after ten days in the third), and they have been discharged with decided improvement in their exercise tolerance.

Table 1.—*Type of Stenosis and Surgical Result in Patients with Tetralogy of Fallot*

Case		Age (Yr.)	Type	Pulmonary Artery Pressure Before	After
1	M. B.	3½	Valvular	11	30.8 (mm. Hg)
2	H. C.	12½	Valvular	2	33.6 (mm. Hg)
3	R. B.	7	Valvular	Not taken	
4	M. R.	18	Valvular	2	48 (cm. H₂O)
5	K. K.	3	Infundibular	Not taken	
6	D. J.	4	Infundibular	Not taken	
7	L. F.	3	Infundibular	[illegible]	31.5 (cm. H₂O)
8	A. S.	21	Infundibular	Not taken	

Although it is obviously too early to draw any conclusions from this small series of cases (the longest postoperative observation is six months), certain generalizations are apparent. The direct ventricular approach to congenital pulmonary stenosis is entirely feasible. With application and a certain dispatch on the part of the operator, it can be done with a low mortality. There were no deaths in this series. The immediate and early results have been excellent, and without doubt our results have equalled and even surpassed those we obtained by the shunt procedures. It is mandatory, however, that enthusiasm for a new procedure be tempered by a consideration of the possible late complications which might arise to confound the enthusiast. A number of questions are unanswerable at present and must await the passage of time and further careful evaluation.

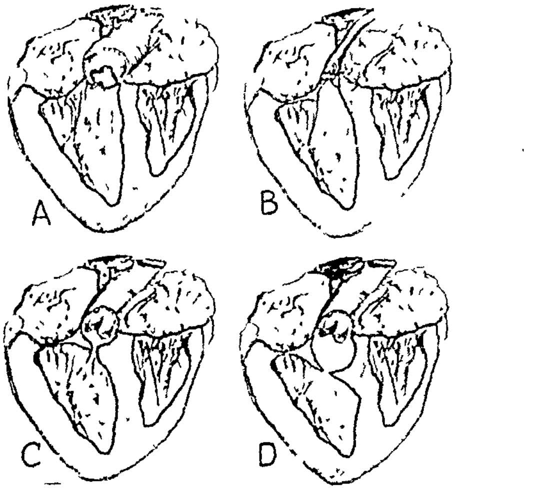

Fig 1—Types of pulmonary obstruction encountered in the tetralogy of Fallot: *A*, pure valvular stenosis; *B*, pulmonary artery hypoplasia with biscupid valve and subvalvular stenosis; *C*, high infundibular stenosis with normal valve, and *D*, low infundibular stenosis with normal valve The other pathological components of the tetralogy of Fallot are not shown (*B*, *C* and *D*)

Does the direct division of a fused pulmonary valve by the method described produce appreciable regurgitation, and will the bicuspid nature of the cusps withstand the rigors of the continued and increasing ventricular output? Will such a valve be subject to the eventual deposition of bacterial thrombi as in subacute bacterial endocarditis? Will the newly formed cusps eventually fuse or the infundibular channel fibrose and contract? There are no data available to satisfactorily answer these obvious and most pertinent queries. Experiences with a somewhat similar type of procedure—in mitral stenosis—with a two and one-half year period of observation have shown that if early regurgitation is not appreciable its late development need not be feared; bicuspid valves can withstand much higher vascular pressures than are present in the right side of the heart; divided cusps which are constantly in action show little tendency to agglutinate in the absence of either insidious (rheumatic) or apparent infection when kept open by an almost constant vascular stream. The infundibular channel should not close for the same reasons provided an adequate amount of tissue has been

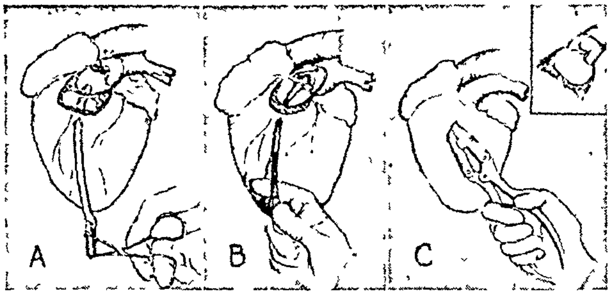

Fig 2.—Methods for direct surgical relief of pulmonary obstruction in the tetralogy of Fallot *A*, Brock punch in infundibular stenosis, *B*, Brock knife in valvular stenosis, and *C*, Glover rongeur in infundibular stenosis.

removed No one can even postulate the probable incidence of superimposed bacterial infection. Suffice it to say that when one has the means to directly relieve congenital pulmonary stenosis and thereby not only to provide a more normal circulation but by such surgery to minimize or directly counteract in great measure the presence of the associated interventricular septal defect and overriding aorta, such possibilities must be explored to the uttermost. This is preferable to placing complete reliance on an added shunt, which at best is contrary to the very nature of the vascular system it is designed to improve. Complete data on cases briefly described herein are given elsewhere.[20]

ACQUIRED VALVULAR DISEASE

In the near future by far the greatest field of intracardiac surgical endeavor will be concerned with the problems of acquired rather than congenital disease, a mirror image of conditions as they exist today. White [21] has estimated that 0.5 to 1 per cent of the community at large is affected by valvular disease, particularly in those areas where rheumatic fever is endemic, as in the northeastern part of the United States and northern Europe. In the great majority of persons afflicted with rheumatic heart disease (up to 85 per cent) there develops some degree of deforming valvular damage, the mitral and aortic valves being the commonest sites of involvement. Structural stenosis of these valves is the most serious result of rheumatic infection. It is little wonder, therefore, since stenosis is essentially a mechanical stricture, that surgical intervention should be considered as offering the ideal therapeutic approach provided it can be accomplished with relative safety and without the production of deleterious side effects.

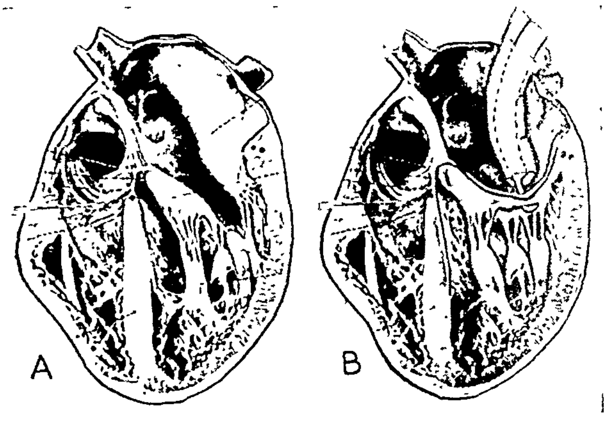

Fig. 3.—Sagittal sections through the heart showing the normal mitral valve (*A*) and diagrammatically the mitral valve in stenosis (*B*). The right index finger bearing the commissurotomy knife has been inserted through the left auricular appendage and the hooked blade engaged on the lateral commissure.

Mitral Stenosis.—The prognosis of an individual case of mitral stenosis depends on many factors: the age of the patient; the severity of the lesion; the presence or absence of other valve defects; the presence or absence of additional rheumatic activity, and the condition of the myocardium. The ultimate outcome, however, is almost invariably unfavorable once the stenotic change gives rise to a progressive pattern. When the diagnosis of early mitral stenosis has been established, the cardiologist can picture and predict with considerable accuracy by both repeated physical examination and observance of the patient's general condition, the structural and symptomatic phases through which a given patient will pass. Treatment by the cardiologist will at once be directed toward the prevention of further rheumatic insults and the support of a myocardium which is vainly attempting to maintain an adequate systemic circulation in the face of an increasing mechanical structure. In such circumstances both the cardiologist and the myocardium are fighting a losing battle. Doubtless just such reasoning prompted Sir Lauder Brunton [22] as early as 1902 to conclude that direct surgical incision of the stenotic valve provided the only logical method of interrupting the relentless chain of events in progressive mitral stenosis. Support of the myocardium by intelligent therapy has offered the only approach to date, but it is treatment of the effects of disease rather than alleviation of its mechanical cause. The ideal approach would be the elimination of the causative agent, rheumatic fever. Failing this, however, the correction of its disastrous cicatricial end result seems most logical.

Since the first section of the mitral ring by Cutler and Levine [23] in 1923 there have been a number of direct attacks on the stenotic mitral valve. The approach and the methods employed have varied. The left auricular appendage,[24] the left ventricle [25] and the left pulmonary vein [6] have been used as sites of entrance. Methods of dealing surgically with the valve have included simple incision of a valve cusp, excision of a portion of the mitral ring, digital dilatation of the stenotic orifice and valvuloplasty designed to resect portions of the valve ring at the commissures of the valve. A complete discussion of the merits and disadvantages of these many approaches and methods has been presented elsewhere.[9b, c] In summary, use of the left auricular appendage as the avenue of approach to the mitral valve is far superior to any other technic. Further, the aforementioned methods of valvular attack were based on the premise that the only hope of relieving the effects of mitral stenosis was to replace it by a regurgitant type of lesion. That this concept was erroneous has been shown repeatedly both in the experimental laboratory [26] and clinically, and to this concept we are unequivocally opposed. Of the approximately 24 patients so treated and recorded in the literature, 14 died promptly and the early survivors were so little improved that the majority succumbed in a relatively short time from their suddenly produced mitral regurgitation—a lesion equally as serious as the original stenosis, at least when produced surgically. We have employed the procedure of commissurotomy—a method in which the individual anatomic valve leaflets are surgically separated—to restore a considerable degree of valve function without the production of additional significant regurgitation. For a complete understanding of the basic principles underlying this surgical maneuver it is necessary to consider briefly the anatomic, pathological, and physiological aspects of the mitral valve as it appears normally and in its diseased state.

Cutler and Beck.[16]

The normal mitral valve may be likened to a truncated cone of thin, flexible membrane. Its base is attached at the left atrioventricular ring, and its apex extends into the left ventricle. The apex and the outer surface of the apical half of this cone are suspended by numerous guy wires (chordae tendineae) attached to papillary muscles arising from the ventricular wall near the ventricular apex. The chordae tendineae are grouped more heavily in two areas of the mitral apex, at either side. These areas represent both the anatomic fusion of the two components of the valve (an anteromedial and a posterolateral leaf) and the corners of the apex on which the leaves fold themselves (fig. 3 *A*). When modified by rheumatic disease, these points of folding become the "commissures." The plane of flattening is oblique (with the patient in the supine position), running from the left anterolateral portion of the valve posteromedially. The anterior or anteromedial valve cusp is larger than the posterolateral; it is continuous with the posterior portion of the intracardiac aortic wall. During auricular systole the posterior or posterolateral cusp lies well away from the ventricular wall. During ventricular systole the ventricular wall may approximate and support it. Thus mitral regurgitation is primarily a defect or dysfunction of the anteromedial valve cusp. A defect of the posterolateral cusp produces limited regurgitation rather than an uncontrolled reflux of blood, as seen when a defect in the continuity of the anteromedial cusp prevents normal deflection of the ventricular output into the intracardiac aorta. The papillary muscles contract synchronously with the ventricle, drawing the chordae tendineae taut, thus preventing the valve leaflets from becoming inverted or displaced backward into the auricle.

In rheumatic disease the mitral valve develops numerous minute cauliflower-like vegetations (1 to 2 mm in diameter) in a row along the line of closure of the valve. Healing leads to the formation of scar tissue. With repeated infection and healing there is gradual development of fibrosis, thickening, and narrowing and shortening of the apical portion of the valve cone. This scarring and narrowing may be very limited in extent and may resemble merely a purse-string puckering of the valve orifice. In other instances the disease involves one fourth to three fourths of the cone, leaving a flexible margin along its base (fig. 4). In far-advanced disease the whole valve becomes a rigid, completely inflexible, often calcified structure resembling a hard, ovoid plaque surrounding a small fish-mouth slit. Most physicians, and even many pathologists, think of such extreme deformity as classic and the rule in mitral stenosis. We have found this condition in only five of our 50 cases.

Usually mitral rheumatic disease hardens or fixes the apex of the mitral cone in the infolded or flattened position so that the commissures become an anatomic reality. Thus stenosis is produced, offering pronounced resistance to the passage of blood from the left auricle into the left ventricle. Some degree of regurgitation through the mitral slit during ventricular contraction is common. Not infrequently mitral rheumatic disease hardens and shortens the valve cone to a point where the leaves cannot be approximated. Such cases of predominant mitral regurgitation are less common than those predominantly stenotic and at the present time are not amenable to surgical correction.

Mitral stenosis of any degree interferes with the filling of the left ventricle and with the maintenance of normal systemic cardiac output. Many hearts with mitral stenosis are unable to increase their output over and above resting body requirements. Any appreciable amount of work will quickly cause patients with this condition to become fatigued or dizzy and even momentarily to lose consciousness. Concurrently, since the egress of blood from the left auricle is impaired, increased pressure within and great dilatation of this chamber results. The high intra-auricular pressure is transmitted to the entire pulmonary vascular system and thence to the right ventricle (fig. 5). A chronic pulmonary hypertension ensues, with nocturnal or exertional pulmonary edema (dyspnea), rupture of pulmonary capillaries (hemoptysis) and failure of the right side of the heart (enlarged liver, ascites and peripheral edema).

Commissurotomy: As previously stated commissurotomy, a term suggested to us by Dr. Thomas Durant of Philadelphia, is the procedure we have employed to reestablish a pronounced degree of normal mitral valve function. Our present operative technic is simple and direct. It has been described in detail in previous publications.[27]

Commissurotomy consists of an operative approach through the left posterolateral chest wall with the patient in the right lateral position. The pericardium is incised longitudinally 1 cm. anterior or posterior to the phrenic nerve. The auricular appendage, usually distended but occasionally of normal size or even contracted, now protrudes from the pericardial sac. A purse-string suture of heavy braided silk is passed about the appendage at its base. A noncrushing clamp is closed over the base of the appendage, and a generous portion of its tip is amputated. Two gloves are worn on the operator's right hand. The blade of the commissurotomy guillotine knife is inserted between the gloves on the index finger (the tip of the outer glove has been removed and an opening made at the base of the index finger), and the finger is inserted into the left auricle as the clamp is released and as the purse-string suture is drawn taut about the finger. The finger is well tolerated by the auricle and causes no disturbance to the circulating blood. The valve is quickly and easily located. Its structure can readily be appreciated; the size of the orifice and the location of the commissures are determined. The knife is now protruded through the opening and the hooked blade engaged on the anterolateral commissure (fig. 3 *B*). A backward stroke with the left hand on the knife handle or approximation of the guillotine blade usually divides the commissure adequately the first time. The finger again palpates the opening and gently dilates it. If the cut in the commissure does not extend well into normal valve tissue through the fibrotic ring, another cut is made under direct digital guidance. In patients who have a rather soft valve orifice decidedly diminished in cross-sectional area, simple opening of the lateral commissure is sufficient. In patients with a rigid, fixed and sometimes calcified valve, incision of the medial commissure also may be necessary. This is accomplished by pronating the hand, engaging the medial commissure and repeating the maneuver already described.

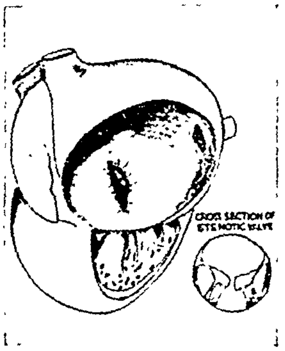

Fig. 4

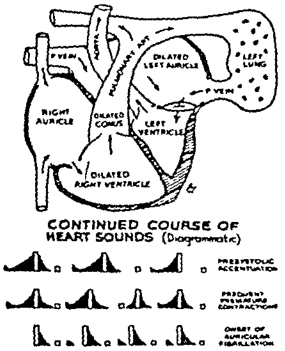

Fig. 5

Fig. 4.—Pathological conditions in late mitral stenosis. Note the decided fibrosis (possible calcific deposits) of cusp margins, extensive fusion of valve commissures, papillary muscles and chordae tendineae decidedly hypertrophied and contracted, and the pronounced dilatation of the left auricle, with early hypertrophy of the right ventricle. In the cross section of a stenotic valve note the induration along cusp margins, with the base of the valve relatively normal.

Fig. 5.—Physiological representation of cardiopulmonary vascular changes in mitral stenosis, showing the continued course of heart sounds and the progressive changes as seen in early adult life.

The finger and knife are now withdrawn from the auricle as the purse-string suture is tied securely, preventing loss of more than a few cubic centimeters of blood. The cut edge of the appendage is oversewn and the lumen of the appendage obliterated. There should be no disturbance of the systemic circulation and few, if any, circulatory irregularities throughout the procedure.

---

[27] Footnote 9b, c and d.

Such a technic has the great advantage of direct digital guidance. It should not produce any significant amount of regurgitation because a considerable measure of valve function has been restored to prevent the reflux of blood during ventricular systole. That it effectively accomplishes the desired result is shown not only by decided clinical improvement but also by objective physiological studies. An abstract of the early cases in which this technic was used has appeared in previous communications.[9a, b]

Results: Commissurotomy by the technic described has been performed in 50 cases with eight fatalities (table 2). In the first of these a modified scalpel was employed, as our present hooked knife and guillotine modifications had not been perfected. Attempts to incise the commissures were attended by repeated disengagement of the blade as it rode over the fibrotic valve, resulting in an inadequate incision extending only a few millimeters into the scar tissue. The patient died on the sixth postoperative day in pulmonary edema from unrelieved mitral stenosis. Death occurred in cases 4 and 5 at a time when the proper technic for the management of the auricular appendage was being perfected. One patient died on the eighth postoperative day from a cerebral embolus originating in the unobliterated lumen prior to the routine use of a purse-string ligature at the base of the appendage. The other succumbed within twenty-four hours from hemorrhage through the purse-string ligature (mass ligature) before the importance of simultaneous obliteration and oversewing of the cut tip of the appendage was appreciated. Since the incorporation of these two steps into our surgical routine further disasters of this kind have not occurred.

TABLE 2.—*Commissurotomy for Mitral Stenosis, Mortality June 1948 to June 1950*

Year	Number of Cases	Number of Deaths
1948	5	3 (60%)
1949	21	3 (14.2%)
1950	24	2 (8.3%)*
Total	50	8 (16%)

* One by digital fracture of obstructive tissue and not the recommended incisional commissurotomy.

The five remaining fatalities all resulted from inadvertent but improper management of the valve itself and may be attributed for the most part to the production of immediately recognizable regurgitation at the time of surgical intervention; such regurgitation may be rapidly fatal, as in cases 26 and 44, in which death occurred within three hours as a result of an extensive tear just anterior to the lateral commissure caused by digital fracture of the obstructive tissue. The usual commissurotomy incision with the guillotine could not be made because the small size of the auricular appendage would not admit both finger and knife—a rare condition. The deleterious effects of acute regurgitation may be more prolonged and may be clinically manifest by the shocklike picture of peripheral vascular collapse. In case 10 the patient succumbed after four days in such a state despite intensive treatment designed to combat the usual shock syndrome. The two remaining fatalities (cases 36 and 16) occurred after three and four weeks, respectively, from relentless and increasing cardiac failure. In case 36 tearing occurred across the posterior cusp just posterior to the lateral commissure as traction was being made. In case 16 the mitral orifice was eccentrically placed and there was no lateral commissure; this necessitated a long medial incision—a dangerous and in this instance fatal procedure. One additional patient (case 14) contracted a severe upper respiratory infection involving the paranasal sinuses initially. All known antibiotics were used without effect. Bronchopneumonia developed, and death occurred in one month from overwhelming infection. This patient had enjoyed four postoperative months of freedom from the crippling effects of her previous mitral stenosis prior to this disaster. Her case is not listed as an operative mortality. Unfortunately, permission for an autopsy was not granted.

Forty-one patients on whom commissurotomy was performed are living and well at the present time. Twenty of these are considered to have excellent results based on the clinical disappearance of all presenting symptoms in each instance, the physiological demonstration of reduced pulmonary vascular pressures in many and the reduction of left auricular and over-all heart size in the majority. Twenty-one are improved according to these criteria. Five of this group had valves so severely damaged and distorted as to be considered essentially inoperable, and little return of valve function could be obtained although the valve orifices were partially opened. Obviously extensive improvement cannot be expected in these patients and their course, initially surprisingly good, will eventually be unsatisfactory. The remaining 16 patients may well continue to improve, as sufficient time has not elapsed in most instances for maximum benefit to have been derived.

Criteria for Selection of Candidates for Commissurotomy: The indications and contraindications for commissurotomy must be considered together. Both must change as experience dictates. The following criteria for the selection of cases have been recommended by Dr. George Geckeler, chief of cardiology, Hahnemann Medical College and Hospital, whose preparation and postoperative care of these patients has contributed immeasurably to the success of this surgical venture:

Most Favorable

1. Patient below age of 40.
2. Normal sinus rhythm and a presystolic accentuation of a late mitral diastolic murmur.
3. Systolic murmur, if any, of minimal intensity.
4. Pulmonic second sound accentuated not more than 1 plus.
5. No previous hemoptysis and no previous failure.
6. A good response to exercise tolerance test.
7. Right axis deviation and no left ventricular enlargement.

Less Favorable

1. Patient below age of 45.
2. Auricular fibrillation and a midlate decrescendo diastolic murmur.
3. Pronounced left auricular enlargement with moderate right ventricular enlargement.
4. Fair response to exercise tolerence test.
5. Electrocardiogram may show some T wave change indicative of myocardial damage.
6. No history of previous failure.

Least Favorable

1. Patient below age of 50.
2. Auricular fibrillation with a late decrescendo diastolic murmur.
3. A short, not more than grade 2, rough systolic murmur.
4. Two plus accentuation of the pulmonic second sound.
5. Fair to poor response to exercise tolerance test.
6. Previous failure should have been readily controlled.
7. Embolic phenomena may have been present.

8. There should be no more than minimal mitral insufficiency as shown physiologically by pressure curves and roentgenologically by little increase in size of left ventricle.

Inoperable

1. Patient above age of 50, except in rare instances.
2. Active rheumatic state.
3. Presence of unremedial failure or gallop rhythm or recent pulmonary infarction.
4. Aortic valve involvement of significant degree.
5. Appreciable degree of left ventricular enlargement.

Comment: It may be stated that in a case otherwise suitable for mitral commissurotomy, not infrequently the presence of recent and recurring arterial embolic phenomena is an urgent indication for surgical intervention. Ligation of the left auricular appendage has completely curtailed the recurrence of such episodes in 15 cases in this series. There was but one death (unrelated to embolism) in this group, and it has been unnecessary to give patients anticoagulants at any time during the postoperative period. As previously suggested,[9b] it may well be that surgical obliteration of the auricular appendages will prove to be the proper approach to the management of systemic or pulmonary embolization in many cases of auricular fibrillation unassociated with mitral stenosis.

Long term follow-up alone can supply the ultimate answer to the effectiveness of commissurotomy. From observations over the past two and one-half years it may be stated that surgery would appear to have an increasingly prominent place in the treatment of mitral stenosis and at the present time offers the only definitive solution to the problem.

Aortic Stenosis.—Emboldened by a reasonable measure of success with the surgical alleviation of stenosis of the mitral and pulmonary valves, it was natural that attention should be turned toward their counterpart in the aortic valve. Interest in this phase of valvular surgery was initiated by the enthusiasm and efforts of the late Horace Smithy, whose untimely death resulted from the rapid devastation of the diseased valve under discussion. It became apparent at once that the lessons learned and the approaches employed in the development of previous intracardiac surgical technics could not be transposed to the aortic valve because of the latter's variances in anatomic structure and relationship to vital coronary pathways. Nevertheless, certain broad patterns for investigation suggested themselves as a result of experiences encountered in this earlier experimental and clinical phase of valvular surgery.

Pathological and Physiological Considerations: The pathological basis of aortic stenosis is varied and complex. It appears that the primary defect in the rheumatic type is an early fusion of the three valve cusp margins. The free edges of the valve cusps are thickened, rolled and eburnated (fig. 6 A, insert). They may frequently contain calcium, but even in its absence they are extremely hard and tough. The valve leaflets themselves vary greatly but invariably are thickened and in most fixed specimens appear rigid and unyielding. In extreme cases the entire aortic valve may be considered as a rigid orifice surrounded by a calcified plaque that has lost all semblance of its original tricuspid nature. The fresh specimen, however, usually reveals a considerable amount of flexibility of the cusps themselves, especially near their attachments to the aortic wall. In this respect the pathologic condition resembles that found in the average case of mitral stenosis.

The disturbed physiological condition in extreme aortic stenosis is apparently due to the slow ejection of a small amount of blood with each contraction of the left ventricle. As a result the systolic blood pressure does not reach high levels but is sustained and maintained longer than is usual. Diastolic pressures likewise are relatively high, so that the pulse pressure differential is small. Coronary flow seems reduced more by the diminished volume of blood in the aorta than it is either by pressure changes or by intrinsic disease in the coronary system. Naturally, the coronary vascular needs of the left ventricle are increased by the large bulk of musculature contracting partly isometrically against the aortic obstruction. This extra work load increases the relative inadequacy of the coronary flow and partially explains the anginal or coronary type of pain so often encountered in these cases.

Patients with uncomplicated aortic stenosis are not primarily dyspneic unless congestive failure has supervened. They become progressively disabled as their cardiac stroke output diminishes with increasing stenosis. Eventually even the slightest exertion produces dizziness and fainting. Persistence in exertional effort leads to greater discrepancy between supply and demand, both systemically and with regard to coronary flow. In all probability this may explain the frequency of sudden death after relatively moderate effort in patients with this type of lesion.

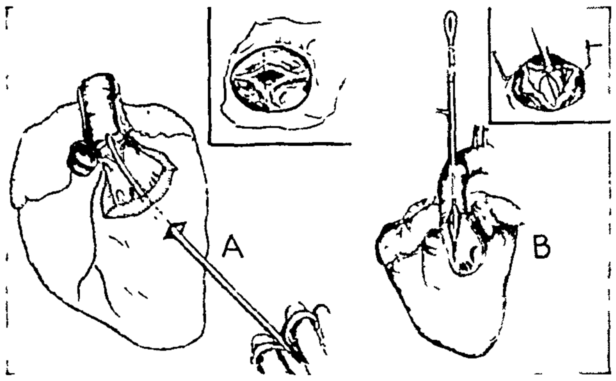

Fig. 6.—Left ventricular approach (*A*) to the aortic valve using instrument with retractable diamond shaped cutting blades. The insert depicts fusion of valve cusps in aortic stenosis and the line of incision. Cervical approach (*B*) to the aortic valve through the right common carotid artery, innominate artery and ascending aorta. The insert shows the effect of the dilating instrument.

Experimental Considerations: The approach to the problems of stenotic valvular disease in the experimental laboratory is fraught with many difficulties. The experimental animal does not have valvular stenosis, nor can a reasonable facsimile of the human pathological picture be produced by methods yet devised. Therefore animal experimentation cannot follow the usual, accepted form but resolves itself into methods of surgical technic designed either to approach the valve itself or to by-pass it by involved methods of vascular anastomosis. Study of human heart specimens obtained at autopsy is likewise unsatisfactory because they usually represent extreme states of disease—a distortion of the conditions which may exist at the time when surgical intervention could reasonably be contemplated. Further, because fixation of the tissues has destroyed certain important functional components such as mobility, bizarre conclusions are drawn

The possible surgical approaches to the problem of aortic stenosis seem to take one of the following four courses (1) replacement of the damaged valve by a section of transplanted aorta containing normal valves, (2) by-passing of the diseased valve by aortic transplants containing normal valves, (3) insertion of a mechanical valve, or (4) direct surgical attack on the stenotic valve itself The possibilities of each of the first three (indirect) methods have been extensively explored experimentally in our laboratory and by others [28] Although phases of this work are still under consideration, preliminary reports have been presented elsewhere [illegible] and will not be repeated in this publication It is sufficient to state that only occasional and unpredictable success has been attained by these experimental efforts and that the results do not warrant clinical trial at this early date Operative hemorrhage the maintenance of unobstructed coronary flow, the viability of tissue and valves so transplanted and many other problems have yet to be satisfactorily solved

Direct Valvular Approach It would seem reasonable that application of the methods successful in clinical mitral and pulmonary valve surgery might offer a ready solution Certain inherent difficulties immediately arise, however, posed primarily by the nature and anatomic position of the stenosed aortic valve It lies deep within the substance of the greatly hypertrophied left ventricle, the coronary ostiums and vessels are in close proximity, and no ready-made avenue for digital approach such as the auricular appendage is available Incision through the myocardium close to the valve in the outflow tract of the left ventricle for the introduction of the finger or instruments is followed by excessive and uncontrollable hemorrhage Similarly, approach through the aortic wall just distal to the valve is attended by the same danger However, it is altogether feasible to approach the valve at greater distance both from the ventricular and from the aortic poles as shown experimentally by Smithy and both experimentally and clinically by us

Since the pulmonary and aortic valves are similar in construction and in method of action, the thought of performing a Brock type of operation for aortic stenosis seemed attractive Therefore on March 9, 1950 at the Episcopal Hospital F B, a white woman aged 26 with extreme aortic stenosis, was subjected to surgical operation With a specially devised instrument equipped with retractable diamond-shaped cutting blades, entry into the left ventricle was made near its apex (a low pressure area as compared to the outflow tract) and the instrument guided into the stenotic valve orifice (fig 6 *A*) The retractable blades were opened and the valve was cut vertically by pulling the instrument back into the ventricle Although the wound was rapidly sutured, almost immediately the heart rate slowed and soon contractions ceased despite stimulation, rapid blood transfusion and prolonged cardiac massage Autopsy revealed that the knife had been well placed and that despite the diffuse calcareous nature of the valve it had been divided into two halves It was evident, however, that appreciable regurgitation had been produced, a condition incompatible with life when suddenly superimposed on diseased tissues Attempts to apply the technics that were successful for the pulmonary and mitral valves had failed initially, and there was no reason to suppose that persistent application of the same principles would meet with a better fate There remained the possibility of modifying the method of Tuffier,[12] who in 1914 successfully dilated the aortic valve of a young man with severe and progressive aortic stenosis By invaginating the wall of the aorta just above the valve and pushing it into the stenosis on the forefinger, he was apparently able to accomplish dilatation of the valve sufficient to bring about reversal of the progressive course of this patient's disease for as late as 1924 the patient was reported living and improved On reexamination of our specimens of aortic stenosis with the possibility of dilatation in mind, it was again noted that the free edge of the cusps of the valve appears to bear the brunt of the disease process The edge is thickened, indurated and tough, often calcified By simple forceful dilatation in the laboratory it was possible to tear open one or more of the sealed commissures without injury to the valve cusp itself Such an opening should produce little if any additional regurgitation, since the cusp as a whole will function better after mobilization True, it would be unusual for all three commissures to tear open with restoration of essentially normal valve function However, the powerful hypertrophied left ventricle, able as it is to compensate until veritably only a trickle of blood can pass the aortic barrier, will readily respond to even moderate relief of the obstruction

We therefore devised an instrument that is shaped like a large pencil with a blunt point This is inserted through an incision in the neck into the lumen of the right common carotid artery It is gently guided through the innominate artery into the ascending aorta and soon impinges on the aortic valve The valve is readily recognized both by resistance to further passage and by the direct transmission of the cardiac movements to the operator's hand through the instrument The valve orifice can readily be located, the instrument engaged within the narrowed lumen and inserted well into the ventricle (fig 6 *B*) The dilating mechanism near the tip is then gently opened by a turnscrew on the handle of the instrument, gradually dilating the cusps to or past the point of commissural separation Blood flow through the aortic orifice is maintained by a lack of continuity of the dilating surface The instrument is then closed and removed, the carotid incision is repaired by a continuous suture of arterial silk

This operation has been performed recently on two patients with multivalvular lesions, one of which was severe aortic stenosis Both patients, although far advanced in the course of their disease and in relatively poor condition, withstood the procedure well Postoperatively both presented objective evidence of enlargement of the aortic valve orifice, and both appear clinically improved Because of associated myocardial disease and coexistent mitral regurgitation, neither was considered suitable for major thoracotomy and direct attack on the heart Both patients underwent operation recently and have not reached a point at which significant conclusions can be drawn regarding the eventual effect of their valvular dilatation

SUMMARY AND CONCLUSION

Our entire experience with the surgical management of stenotic valvular disease has been reviewed The fact that pulmonary valvular and infundibular stenosis can be relieved by the direct surgical approach as devised by Brock and modified herein has been confirmed Initial results with the direct ventricular approach are at least comparable with those of earlier shunt procedures, and the prospect that the patient will have more nearly permanent relief and a more certain future after the direct approach seem to outweigh present doubt as to the eventual physical havoc that may result from the surgically produced shunts of earlier technics.

[28] Campbell J M An Artificial Aortic Valve J Thoracic Surg **19** 312, 1950 Hufnagel C A in the Thirty Fifth Clinical Congress American College of Surgeons Chicago Oct 17 21, 1949 Bailey and others [29]

Commissurotomy accomplishes relief of mitral stenosis by restoring a considerable degree of valve function without the production of significant mitral regurgitation. That this type of surgical intervention can be performed with a reasonably low mortality has been demonstrated. There has been no return of the stenotic state detectable clinically or physiologically in two early cases followed for a period of two and one-half years or in any more recent cases.

In aortic stenosis dilatation of the aortic valve would appear to be the surgical treatment of choice at the present time. Whether this surgical objective is best achieved from the aortic or ventricular approach is conjectural. Considerable time must elapse for evaluation of present methods.

ADDENDUM

Since this paper was submitted for publication many additional patients have been treated surgically. The total cases to date (October, 1950) include: pulmonary stenosis in tetralogy of Fallot (consecutive), 15 (six infundibular and nine valvular) with two deaths (one infundibular and one valvular); mitral stenosis, 86 (60 so far in 1950) with four deaths, mortality 6.6 per cent, and aortic stenosis, five with two deaths

CONVERSION OF THE AURICULAR APPENDAGE INTO A LEAKPROOF VALVE TUBE FOR INTRACARDIAC SURGERY

SAMUEL ALCOTT THOMPSON, M D
New York

One of the most important steps in successful intracardiac surgery is the prevention of hemorrhage from the heart. Control or prevention of cardiac hemorrhage can be accomplished in a number of ways The simplest and most frequently used method is a purse-string suture, or opposing purse-string sutures around the wound of entrance.

I am presenting a method for the control or prevention of cardiac hemorrhage during intracardiac surgery by the creation of a valve tube, using the auricular appendage. To my knowledge this method has not been previously described. It was perfected in the surgical research laboratory on dogs and has been used on two human beings.

The auricular appendage lends itself admirably to the creation of a valve tube because its walls are thin and pliable and it can be easily elevated or invaginated into the cavity of the auricle. The appendage hangs down on the outside of the auricle like a dog's ear and is actually a small secondary extra-auricular chamber of the heart. The opening of the appendage into the auricle is large, and when the tip end of the appendage is held away from the side of the auricle it forms an irregular flattened triangular or cone-shaped pocket.

Conversion of this cone-shaped pocket into a valve tube which is leakproof and which can be used without haste and repeatedly at any one operation for intracardiac digital or visual examination or for surgical intervention is accomplished by placing two sets of opposing purse-string sutures.

After the pericardium is opened, the tip of the appendage is picked up and held steady by a noncrushing clamp. A site is now selected on the appendage, just proximal to the tip, which is judged to be of sufficient diameter to admit the instrument or palpating finger. At this site opposing purse-string sutures are placed. The suture material which I prefer is number 0000 black silk on an atraumatic needle. The first suture is on the upper or outer surface of the appendage and consists of three bites. The first needle bite is near the edge of the appendage on its upper surface, the second needle bite is in the center of the upper surface and the third bite is near the opposite edge of the upper surface as is shown in figure 1 *A*. The second purse-string suture is placed in a similar manner on the under or cardiac surface of the appendage at a point directly opposite the first suture. Since the purpose of these sutures is to form a valve which can be repeatedly opened and closed, their proper placement is important. The first set of purse-string sutures forms the outer valve.

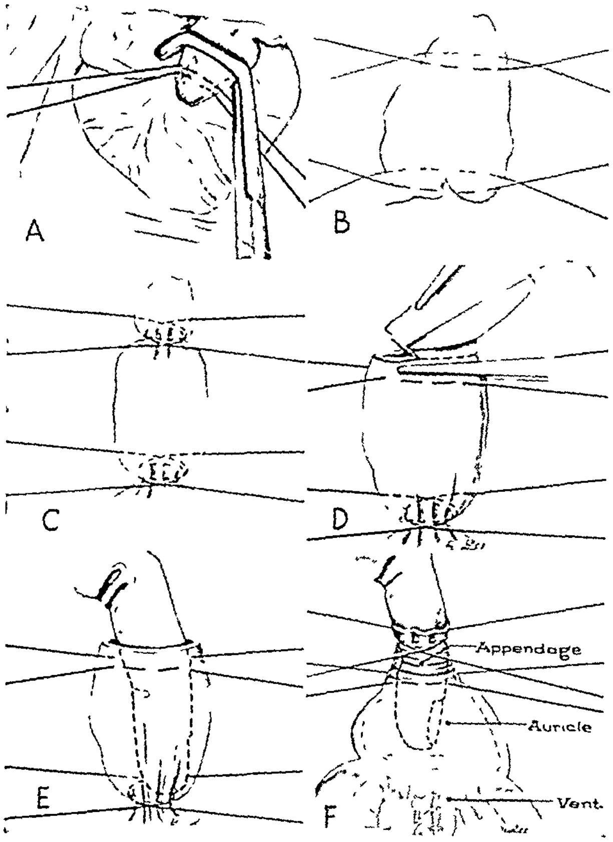

Fig 1 —*A*, opposing anterior and posterior purse string sutures are placed near the tip of the appendage The sutures go through the entire thickness of the wall of the appendage and form the outer valve *B*, a second row of anterior and posterior opposing purse string sutures is placed near the base of the appendage to form the inner valve The appendage is elevated to show the tubelike effect *C*, creation of the valves is accomplished by a purse string pull on the opposing sutures When the sutures are relaxed the appendage returns to its normal shape *D*, the inner valve is closed to prevent a leakage from the auricle, and the tip of the appendage is cut off *E*, a finger or instrument is now inserted through the relaxed outer valve down to the closed inner valve of the appendage *F*, when the tip of the finger has reached the closed inner valve, the outer valve is now closed, the inner valve relaxed and the finger or instrument is inserted into the auricular cavity by invagination of the appendage Removal of the finger or instrument is accomplished by reversing the procedure

---

Fellow of the American College of Surgeons

From the Thoracic Surgical Service of the New York Medical College, Flower and Fifth Avenue Hospitals

The second set of opposing purse-string sutures is now placed at the base of the appendage just distal to the auricle. The first suture consisting of three needle bites is placed in a manner parallel to the first suture of the first set, and the second suture is parallel to the second suture of the first set. This second set of sutures forms the inner valve (fig. 1 *B*).

The sutures go through the entire thickness of the wall of the appendage and when pulled in the manner of purse strings will completely approximate the walls at that point and thus act as a valve and close any existing opening (fig. 1 *C*). However, when the sutures are pulled in the opposite direction of a purse string, they pull the walls of the appendage away from each other and tend to relax and hold open any existing opening. Thus the valves may be closed or relaxed at will by merely reversing the direction of the pull on the sutures. These opposing purse string sutures are not tied until the intracardiac surgical procedure is finished. The use of curved and straight clamps and of different size clamps on the suture ends helps the operator to identify each suture at a glance.

When the inner valve is closed by pulling on the second set of sutures in a purse-string manner, this completely occludes the auriculoappendical opening and separates the auricle from the appendage. As long as the inner valve is closed any manipulation or opening distal to this point causes no loss of blood other than the small amount contained in the appendage itself at the time of the valve closure.

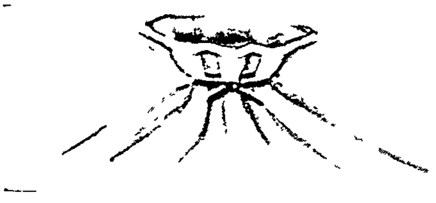

Fig. 2.—At the conclusion of the operation the proximal purse string sutures are tied securely and the part of the appendage distal to this ligature is amputated.

After the two sets of sutures are placed, thus forming an outer and an inner valve and converting the appendage into a tube, the inner valve is closed and held closed by proper suture pull. The tip end of the appendage just distal to the outer valve is now completely cut off by scissor or scalpel, and this opening is relaxed by proper suture pull on the outer valve (fig. 1 *D*). The palpating finger or instrument is inserted through this opening down to the inner valve (fig. 1 *E*). The first set of sutures forming the outer valve is now pulled in a purse-string manner and the outer valve is closed and held closed around the finger or instrument. The inner valve is now released by reversing the suture pull to allow the finger or instrument to enter the auricle and proceed, if desired, through the auriculoventricular valve into the ventricle (fig. 1 *F*). The appendical musculature is thin and pliable and lends itself easily to invagination.

At the end of the maneuver the finger or instrument is withdrawn just distal to the inner valve and this valve is again closed off by proper suture pull. When the inner valve is closed the outer valve is relaxed and the finger or instrument is withdrawn entirely from the appendage. The entrance and exit may be repeated a number of times. When the operation is finished, the sutures forming the inner valve are pulled tight and tied securely, and that portion of the appendage distal to the sutures is cut off completely (fig. 2). Amputation of the appendage after purse-string suture is followed by excellent healing without mural thrombosis.[1]

CONCLUSION

The creation of an outer and inner valve which can be closed or relaxed at will gives the surgeon the opportunity for digital or instrumental examination before and after intracardiac surgery without fear of hemorrhage and without undue haste. The auricular appendage is well suited for the creation of such a valve tube. It is important that the sutures be placed at a definite site and in a definite manner. It is also important that the opening in the distal end of the appendage be large enough to easily admit the palpating finger or an instrument, without stretching or tearing the mouth of the opening.

CORTICAL STEROIDS IN TREATMENT OF CANCER

Observations on Effects of Pituitary Adrenocorticotropic Hormone (ACTH) and Cortisone in Far Advanced Cases

SAMUEL G. TAYLOR III, M.D.
JOHN P. AYER, M.D.
and
ROGER S. MORRIS Jr., M.D.
Chicago

It is now well established that androgenic and estrogenic steroids produce temporary regression of malignant tissue of the breast[1] in certain cases and that estrogenic steroids also have an anticarcinogenic effect on prostatic cancer.[2] There is also some evidence that progesterone may have a similar effect on carcinoma of the cervix,[3] breast[4] and prostate.[5] When pituitary adrenocorticotropic hormone (ACTH) and cortisone became available for clinical trial, it seemed logical to attempt to evaluate their effect on various types of malignant lesions. Murphy and Sturm[6] reported favorable results on transplanted leukemia in rats with

pituitary adrenocorticotropic hormone or adrenal cortical extract. Heilman and Kendall[7] produced an arrest of the growth of malignant lymphoid tumor in the mouse with the administration of cortisone. Pearson and others[8] have reported temporary remission in Hodgkin's disease, acute leukemia and chronic lymphatic leukemia in man after use of the two drugs. We have previously reported[9] symptomatic improvement in cancer of the trachea, endothelial myeloma (Ewing's tumor) and carcinoma of the breast during pituitary adrenocorticotropic therapy. However, augmentation of breast carcinoma seemed to occur in one patient. Serious psychic changes occurred in three patients during prolonged therapy.

CLINICAL MATERIAL

The effect of pituitary adrenocorticotropic hormone and cortisone was studied on 26 patients with far advanced malignant disease. All but two of the patients had previously had surgical treatment and/or irradiation. Some patients in the lymphoma group had had extensive nitrogen mustard therapy before starting treatment with pituitary adrenocorticotropic hormone or cortisone. Although the clinical results on the disease process have been favorable in only a few patients, the physiological alteration produced by large doses of these drugs over a relatively long period of time have been of interest and may serve as a timely warning with the increasing availabiilty of these drugs. The following types of neoplasms were treated: 5 carcinomas of the breast, 1 carcinoma of the trachea, 1 carcinoma of the colon, 1 hypernephroma, 1 angioendothelioma (Ewing's sarcoma), 1 neurofibrosarcoma, 1 melanoma, 6 lymphosarcomas, 1 subacute myelogenous leukemia, 1 chronic lymphatic leukemia, 1 acute leukemia, 1 multiple myeloma, 3 Hodgkin's disease and 2 mycosis fungoides.

PROCEDURE

Metabolic balance studies were done on the first few patients, but as it became apparent that no new information was being obtained and that dangerous complications could be predicted adequately by clinical observations and less cumbersome laboratory technics, this was abandoned.

Serum sodium, potassium and proteins, sedimentation rate, hemograms and total eosinophil counts were done. Aliquots were saved for further study where indicated. Results of the Thorn test, 17-ketosteroid excretion and glucose tolerance test were determined for most patients before therapy. These tests were repeated during and after treatment. When feasible, pretreatment and post-treatment biopsies were obtained. Liver function tests and bone marrow aspirations were compared before, during and after therapy in certain patients. Daily weight and fluid balance were obtained.

Pituitary adrenocorticotropic hormone was given every six hours in doses of 25 to 50 mg. and cortisone in doses of 100 to 600 mg. daily in one or more doses. One patient inadvertently received a single injection of 175 mg. of pituitary adrenocorticotropic hormone. This produced vasopressin (pitressin®)-like effects but no untoward reaction. All patients were placed on a low sodium diet and given 3 to 4 Gm. of potassium chloride daily during treatment with the agents.

RESULTS

The clinical response of most patients was reduction in fever, if present, increased appetite and improved strength and well-being. At times the effects were dramatic and appeared usually within 48 hours after starting pituitary adrenocorticotropic therapy and within four to six days after starting treatment with cortisone. This improved state lasted until side effects from long continued therapy ensued or complications produced by the progress of the neoplastic disease developed. Patients hitherto bedridden, vomiting and requiring heavy doses of narcotics were able to become ambulatory, reduce or stop their reliance on narcotics and eat astonishing meals within 48 hours after starting to take the former drug, or a few days later after starting to take the latter. Progressive anemia frequently was controlled, and in several patients the red blood cell count and hemoglobin level rose slightly. Results of liver function tests, if abnormal before treatment, improved. Elevated sedimentation rates were reduced, and jaundice disappeared.

These clinical signs of improvement were temporary, and relapse of the patient occurring shortly after omission of therapy was the rule. However, three patients with lymphosarcoma, one with Hodgkin's disease and one with chronic lymphatic leukemia have maintained this improvement as long as three months after omission of therapy. We have frequently been faced with the problem whether complications produced by continued therapy or relapse from omission caused more distress to the patient.

EFFECT ON TUMOR GROWTH

In no patient with carcinoma was there evidence of reduction in the size of the tumor with pituitary adrenocorticotropic hormone, although induration and edema around the site of the tumor frequently regressed. In three of the four patients with carcinoma of the breast, treated with this drug, the growth appeared to be augmented, although a carcinomatous ulcer healed in one.

Biopsies were obtained before therapy on four patients with cancer of the breast, and biopsies or autopsies were done immediately following therapy. Before this drug was given these patients had all had therapy: in three it consisted of radiation followed by sex steroids. One patient also had nitrogen mustard therapy, and one had had diethylstilbestrol therapy only. Because of these factors, interpretation of the anatomic effects of the drugs is impossible. No effect on the neoplastic growth could be demonstrated. The cells of the tumor were viable and actively proliferating. Metastases were widespread, occurring in the spleen, pancreas and gastrointestinal tract, bladder and lymph nodes. The spleens of two of the three patients with autopsy showed extraordinary extensive permeation by neoplastic cells (fig. 1), suggesting a decreased resistance of this organ to the neoplastic cell.

One patient (case 2) with carcinoma of the breast who was given cortisone showed reduction in the size of skin lesions with healing of ulceration. Biopsies, however, did not show changes in the malignant cells. Four weeks after omission of cortisone therapy, the lesions again ulcerated and new lesions appeared.

Repeated biopsies taken before, during and after therapy in the patient with carcinoma of the trachea (case 7) showed no cytological change in the tumor, and supraclavicular metastases appeared during therapy along with extension of the tumor above and below the initial site. However, carcinomatous ulceration healed and edema subsided, producing an improved airway. No biopsy was obtained of the liver after therapy in the patient (case 6) with hepatic metastases from carcinoma of the colon, and no appreciable decrease in the size of the liver was observed.

Results with Pituitary Adrenocorticotropic Hormone (ACTH) and

Case	Sex	Age	Disease State	Therapy		Duration of Course of Therapy (Days)	Change in Tumor During Therapy	Clinical Changes During Therapy	Present Status
				Drug	Gm				
1	F	59	Adenocarcinoma of breast, visceral metastases	ACTH	1.24	25	None	Edema, congestive failure and euphoria	Died 10 days after omission of therapy; autopsy
2	F	54	Adenocarcinoma of breast, local and axillary recurrences	Cor.	3.8	23	Reduction in size of skin nodules, no cytological change (serial biopsies)	Euphoria	Living 57 days after stopping therapy; lesions progressing
3	F	44	Adenocarcinoma of breast, visceral metastases	ACTH	3.85	24	Possible augmentation	Schizoid reaction; edema, moon face and hyponatremia	Died 6 days after omission of therapy; high fever, at autopsy, unusual invasion of spleen by neoplasm
4	F	54	Scirrhous carcinoma of breast R., adenocarcinoma; L., visceral metastases	ACTH	2.25	23	Healing carcinomatous ulcer, augmentation of other lesions	Schizoid reaction following euphoria; control of vomiting, fever and pain, improved nutrition; became ambulatory	Died 2 days after omission of therapy, high fever, at autopsy, invasion of spleen as in case 3
5	F	73	Carcinoma simplex of breast, regional metastases	ACTH	1.18	19	Augmentation; no cytological change (serial biopsies)	Edema, congestive failure, moon face and mental confusion	Living 231 days after omission of therapy; mentally normal; lesion stationary
6	M	38	Carcinoma of colon, hepatic metastases	ACTH	2.98	35	None	Reduced fever, improved liver function and appetite; less pain; euphoria	Living 45 days after omission of therapy, nitrogen mustard administered into hepatic artery on omission of ACTH with reduced size of liver, liver function remains improved
7	M	63	Carcinoma of trachea	ACTH Cor ACTH ACTH ACTH	8.8 3.0 1.6 1.2 0.6	90 15 20 15 12	Healing carcinomatous ulcer; no cytological change (serial biopsies)	Relief of bronchial spasm; most signs of Cushing's syndrome, hypomania, *pneumonia on omission*; pigmentation	Living; still receiving repeated courses of ACTH; tumor *progressing*
8	M	23	Hypernephroma; skeletal and visceral metastases	ACTH	1.5	15	None (serial biopsies)	Moon face, edema and acne	Living; progression of disease
9	M	15	Angioendothelioma with metastases	ACTH	4.187	34	Progressively decreasing mitoses and fibrosis (serial biopsies)	Control of fever, vomiting and anemia; most signs of Cushing's syndrome, mental confusion	Died 4 mo. after omission of therapy; no autopsy
10	M	23	Neurofibrosarcoma; pulmonary axillary metastases	ACTH	1.67	20	None	Euphoria; decreased pain; improved movement of affected joint, less induration	Living 30 days after omission of therapy; pain recurring, induration the same
11	M	52	Melanoma, visceral metastases	ACTH	1.7	17	Hemorrhage into abdominal metastases; melanotic infiltration of skin; serial biopsies, no change	Reduction of fever, decreased pain, increased appetite; edema, euphoria and restlessness	Died 49 days after omission of ACTH; at autopsy, no change in the tumor, further progression of disease
12	M	54	Lymphosarcoma	ACTH	2.225	26	Decrease in size of cervical nodes, serial biopsies; no change	Relief of abdominal pain, improved appetite; euphoria, edema and pigmentation	Died 14 days after omission of ACTH; no autopsy; fever, rapid growth of nodes, anemia
13	F	44	Lymphosarcoma	ACTH ACTH	2.235 2.7	26 29	Decrease in size of involved nodes and abdominal masses, 1st course; serial biopsies, no reduction, 2d course	Relief of pain, improved appetite; edema, pigmentation and euphoria	Living on therapy; relapse immediately after therapy, despite nitrogen mustard and radiation; 2d course did not produce clinical improvement
14	F	49	Lymphosarcoma	Cor ACTH Cor.	3.0 1.265 4.0	24 14 20	Decrease in size of nodes with *cortisone; no* change with ACTH; serial biopsies, no change	Decreased abdominal pain, fever and nausea controlled with cortisone, relapse on changing to ACTH; second course of cortisone, no improvement	Died 3 wk. after last course of cortisone
15	F	67	Lymphosarcoma	Cor. Cor. ACTH	3.79 0.710 1.26	27 9 15	Decrease in size of nodes with cortisone; no effect with ACTH, serial biopsies, decreased mitosis	Marked increase in strength; improvement lasted 6 weeks, after cortisone was omitted; no improvement with ACTH	Discharged from hospital in terminal condition died 2 wk. later; no autopsy

Biopsies before and after pituitary adrenocorticotropic therapy on metastatic lesions in the patient (case 8) with hypernephroma revealed no change, and there was no visible evidence of tumor regression. Biopsies of the endothelial myeloma before and after therapy showed the development of areas of necrosis, slightly decreased mitotic activity and proliferative fibrosis at the margins of necrotic areas. These changes had already begun at the time of the first biopsy and were probably due to previous nitrogen mustard therapy. However, two subsequent biopsies showed further decrease in mitosis and increased fibrosis. The biopsy material on the neurofibrosarcoma was unsatisfactory, but no evidence of regression of the tumor was noted clinically.

The one case of melanosarcoma treated with the adrenocorticotropic agent at autopsy displayed widespread, wildly growing metastases. The patient with subacute myeloid leukemia showed no change in the peripheral blood or bone marrow following pituitary adrenocorticotropic therapy. This was also true of a child with acute leukemia. Although there was a decided reduction in the size of the spleen, liver and lymph nodes in the patient with chronic lymphatic leukemia, no changes were noted in the biopsies of the nodes or in the bone marrow aspiration studies. After 14 days of pituitary adrenocorticotropic therapy, the bone marrow studies of the patient with multiple myeloma had shown no change in the percentage of myeloma cells.

Cortisone Therapy on Patients with Advanced Neoplastic Disease

Case	Sex	Age	Disease State	Therapy Drug	Therapy Gm	Duration of Course of Therapy (Days)	Change in Tumor During Therapy	Clinical Changes During Therapy	Present Status
16	M	29	Lymphosarcoma	ACTH ACTH	2 125 2 550	28 31	Decrease in size of liver and spleen	Fever reduced, cough controlled, chest cleared, appetite improved, blood count improved; jaundice cleared, relapsed 2 wk. after 1st course of ACTH, second remission with 2d course; acne, Cushing's facies	Living; returned to work after disability of 1 yr.; liver and spleen not palpable; good health 3 mo after 2d course of therapy
17	F	63	Lymphosarcoma of liver and spleen with ascites	ACTH	1 810	26	Liver biopsy at onset of therapy, not repeated; liver and spleen greatly reduced in size	Sulfobromophthalein excretion improved, increased vigor, edema, euphoria	Living; improvement maintained 35 days after omission of therapy
18	F	57	Advanced Hodgkin's disease (onset 3½ yr prev.)	ACTH ACTH Cor. Cor. ACTH	1 105 0 600 1 8 6 7 1 04	18 3 35 41 14	Decrease in size of nodes during therapy with recurrences within 1 2 wk. after omission (serial biopsies)	Jaundice, itching and fever controlled, severe signs of Cushing's syndrome	Living 217 days after therapy instituted; disease in remission for 1 2 wk after therapy omitted, several times has appeared terminal but improved with course of therapy, in remission 1 wk after omission of therapy
19	M	28	Hodgkin's disease of liver (duration 3 mo)	ACTH	1 705	20	Nodes reduced; liver and spleen decreased in size	Jaundice disappeared; alk phos. from 28 1 to 12 U ; bilirubin from 7.17 to 1 21 mg.; sulfobromophthalein from 44 5 to 9 77% retention, vomiting controlled; size of liver, spleen and nodes decreased; acne, pronounced euphoria	Continues in remission 107 days after omission of ACTH
20	F	24	Hodgkin's disease (duration 3 mo)	ACTH	2 910	37	Pelvic mass decreased in size	Fever and pain controlled; immediate relapse on omission of therapy	Given nitrogen mustard for relapse after ACTH; in remission 2 mo after nitrogen mustard
21	F	34	Chronic lymphatic leukemia (duration 1 yr.)	ACTH	1 700	18	Spleen, liver and nodes decreased; serial biopsy, no change; hemogram unchanged	Increased comfort due to reduction in size of spleen; belligerency developed; WBC rose from 24,000 to 40,000	Hemogram and splenomegaly continued improved 90 days after omission of drug, gradual decrease in lymphocytes and total WBC
22	M	45	Subacute myelogenous leukemia (duration 2 yr.)	ACTH	2	20	Progressive leukopenia	Increased bleeding tendencies; gradual deterioration; development of abscesses; pigmentation	Died 42 days after omission of therapy
23	F	3	Acute myelogenous leukemia	ACTH	0 4	11	No change in hemogram	Progressive downhill course; glycosuria developed 9th day of therapy	Died 6 days after omission of drug
24	F	55	Mycosis fungoides (duration 25 yr.)	Cor. ACTH Cor. ACTH	1 75 0 675 1 95	10 7 8 36	Few lesions healed; most progressed	Slight euphoria and severe edema; congestive failure; serum Na dropped to 119, K rose to 6 1 mEq. with decreased Na and increased K excretion; fulminating infection after omission of ACTH; glycosuria	Died with pneumonia 66 days after institution of first course of cortisone
25	F	55	Mycosis fungoides (duration 15 yr.)	ACTH ACTH ACTH ACTH	3 972 2 575 1 725 3 290	50 30 20 37	Healing of 80% of lesions; no new lesions appeared during therapy; less malignant-looking cells on serial biopsies; relapse with new lesions on omission of drug	Psychosis developed; diabetic acidosis, hypokalemia with ECG changes; Cushing's facies; immediate control of pruritus and fever. Relapse on omission of the drug	Died of pneumonia on omission of ACTH, 254 days after institution of therapy
26	M	58	Multiple myeloma	ACTH	1 5	15	Bone marrow showed no change	Restlessness, increased previous depression; muscular weakness	Unchanged, still receiving ACTH

All three patients with Hodgkin's disease showed major regression in the size of the tumor. One patient (case 18) has been suitable for repeated biopsies. This patient had previously had what was considered maximal radiation and nitrogen mustard therapy. Radiation had been given one month before the biopsy specimen was taken prior to pituitary adrenocorticotropic and cortisone therapy. This showed areas of necrosis, fibrosis, vascular proliferation and endarteritis obliterans, changes which are usually associated with the effects of roentgen and nitrogen mustard therapy. These areas showed little tendency to increase in size with hormonal or cortisone therapy. A profuse eosinophilia was seen in a biopsy from a lymph node over a month after institution of therapy with pituitary adrenocorticotropic hormone.

One patient (case 15) with lymphosarcoma (figs. 2 and 3) had received roentgen therapy to tolerance before treatment with the two steroids. Another (case 14) had not received prior treatment. Both biopsies obtained before therapy were similar and had characteristics typical of the disease. Treatment with cortisone resulted in the following changes:

> There occurred partial but well defined reduction in the size of the tumor, liver and spleen. There were areas of necrosis with surrounding zones of pale, edematous, proliferating fibrous tissue which increased as therapy was continued or repeated. Between the areas of necrosis and fibrosis large islands of actively proliferating neoplastic reticulum cells occurred. These cells were similar to those seen before cortisone therapy, except that the number of mitotic figures appeared to be slightly decreased and the fragility of the cells appeared to be increased with resultant filamentous forms in large numbers. Subsequent pituitary adrenocorticotropic therapy resulted in progression of the changes and occurrence of an unusual edematous mucoid alteration of the collagen.

Measurement of changes in the tumor of the other three cases of lymphosarcoma were based on reduction in the size of the spleen, liver and abdominal masses, which occurred in all to a pronounced degree. These changes have been maintained for 3 months in one and 1 month in another. The abdominal mass, previously proved to be tumor by biopsy, rapidly increased in size two weeks after treatment with the drug was omitted and has not regressed during a second course of therapy.

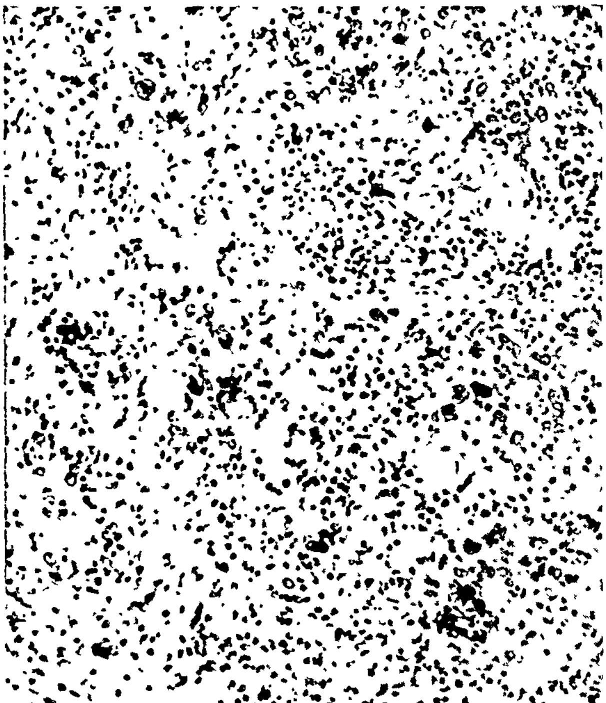

Fig. 1 (case 4).—Spleen demonstrating diffuse permeation of the pulp with metastatic tumor following therapy with pituitary adrenocorticotropic hormone.

Grossly, the lesions of the two patients with mycosis fungoides responded differently to adrenocorticotropic therapy. While one showed pronounced regression and healing of about 90 per cent of the lesions with no new lesions appearing during therapy, the other showed healing of only 10 per cent of the lesions. Cortisone appeared to be of more value to the patient who responded poorly to pituitary adrenocorticotropic hormone:

> Histologically both patients had lesions consistent with mycosis fungoides before treatment. Both patients had received innumerable types of therapy previously, including radiation and antibiotics. Treatment with pituitary adrenocorticotropic hormone resulted in a decrease in acanthosis, a diminished amount and diminished acuteness of inflammatory reaction in the corium, a slightly decreased number of immature reticuloendothelial cells with less mitotic activity and a diffuse proliferative fibrosis similar to that seen in the granulation tissue of healing wounds. The

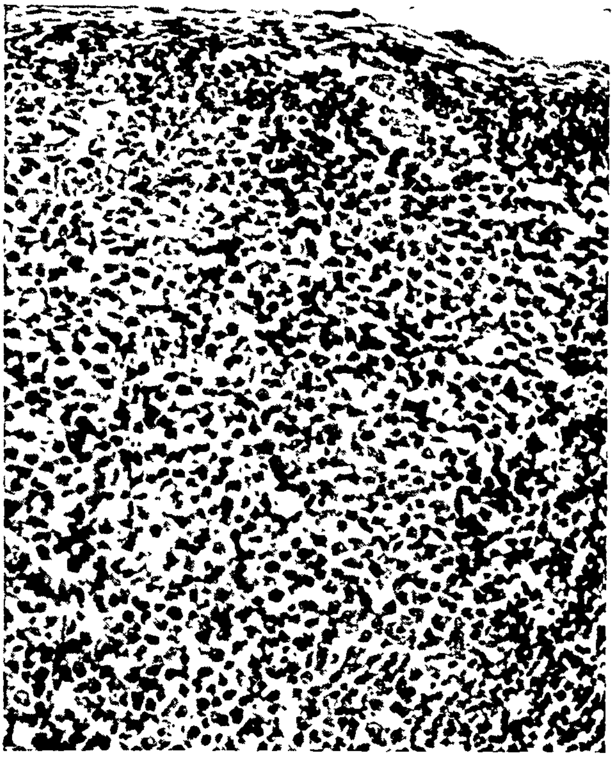

Fig. 2 (case 15).—Lymph node of lymphosarcoma before pituitary adrenocorticotropic hormone and cortisone therapy.

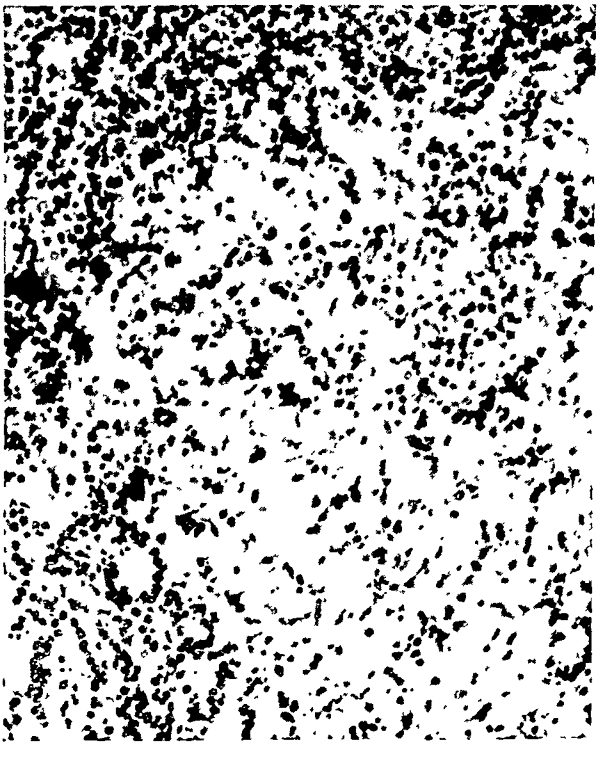

Fig. 3 (case 15).—Lymph node of lymphosarcoma showing progressive fibrosis and necrosis during therapy with the drugs.

inflammatory reaction diminished first in the deeper corium; the first cell to disappear was the eosinophil, followed by the polymorphonuclear leukocyte. Microabscesses of Pautrier in the epidermis also disappeared. The changes noted were of degree only, and the qualitative characteristics of the disease persisted. Correlation of the histological observations to the clinical course was not possible, the changes of the former usually being delayed. Periods without therapy resulted in a slight reversion of the condition to that before treatment. Reinstitution of therapy caused a mild improvement as judged by histological means.

It is difficult to draw conclusions because of the variability of the site of biopsy, the natural course of the disease and the effects of previous therapy. At autopsy both patients had severe pyogenic infections, and one had neoplastic masses in the lymph nodes, liver, lungs and peritoneum as well as the skin.

COMPLICATIONS FROM TREATMENT

The physiological alterations producing complications in our patients with extended pituitary adrenocorticotropic or cortisone therapy can be divided into: (*a*) electrolytic disturbances; (*b*) decreased glucose tolerance; (*c*) mental changes; (*d*) altered response to infection; (*e*) pigment disturbances; (*f*) sexual disturbances, and (*g*) Cushing's syndrome.

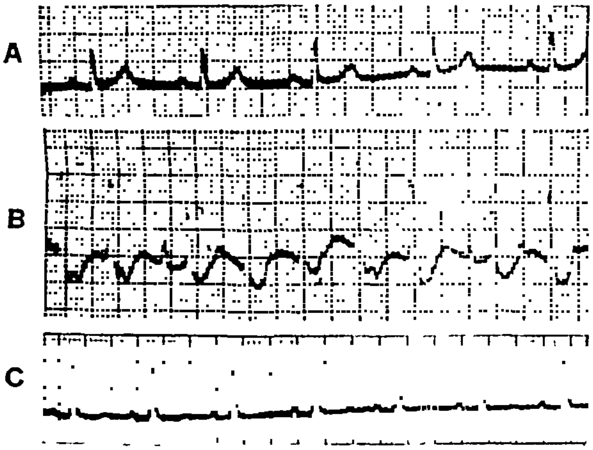

Fig. 4 (case 25).—Electrocardiographic changes in lead 2 during acute hypokalemia produced by prolonged pituitary adrenocorticotropic therapy. Note depression of the S-T segment with inversion of the T wave and progressive auriculoventricular block. *A*, Oct. 26, 1949 the heart rate was 64; the serum potassium level had been 4.1 milliequivalents per liter Sept. 21, 1949. *B*, Jan. 1, 1950 the heart rate was 140 and the serum potassium level 1.8 milliequivalents. *C*, Jan. 7, 1950 the heart rate was 100 and the serum potassium level 4.2 milliequivalents.

(*a*) *Electrolytic Disturbances.*—Disturbances Due to Sodium Retention: Edema occurred in 16 of 25 patients treated with pituitary adrenocorticotropic hormone and four of five treated with cortisone. This produced a serious problem in four patients requiring reduction or omission of the drug. Severe congestive failure was produced in three patients because of this. Hypernatremia did not occur in any patients, but hyponatremia of 112, 119 and 125 milliequivalents of sodium per 100 cc. of serum appeared in two patients despite decreased sodium retention. Hypertension did not occur in any patients.

Disturbances Due to Potassium Loss: Muscular weakness occurred in 19 cases. This may have been due to loss of potassium from the tissues. In two patients hyperkalemia developed despite pronounced potassium loss and evidence of tissue potassium deficiency. In only one patient did there develop acidosis and hypokalemia with typical electrocardiographic changes and the Wenckebach phenomenon (fig. 4). She also had decided glycosuria. Intravenously given potassium and control of the diabetes produced a return to normal electrocardiographic observations.

(*b*) *Decreased Glucose Tolerance.*—A change from normal glucose tolerance curve to a diabetic curve occurred in 11 of 14 patients given this test, both with pituitary adrenocorticotropic hormone and cortisone. Glycosuria and hyperglycemia that persisted for six weeks after the cessation of therapy occurred in a patient with a previously normal glucose tolerance. One patient manifested hypoglycemia after receiving the former drug. The blood sugar level fell to 34 mg. per 100 cc. of blood or less one hour after the patient received 100 Gm. of glucose orally or intravenously on three occasions.

(*c*) *Mental Changes.*—In all but four patients personality changes occurred. Euphoria was noted in 22. This has previously been described in patients treated for rheumatoid arthritis as the result of improved general conditions. Hypomania developed in three patients and frank schizoid reactions occurred in three others. Most patients complained of sleeplessness, restlessness and inability to concentrate. A few stated that their minds became too active. Depressed states frequently followed the above reactions. Two patients became suicidal. In no case, however, did the character change persist over three weeks after discontinuation of therapy.

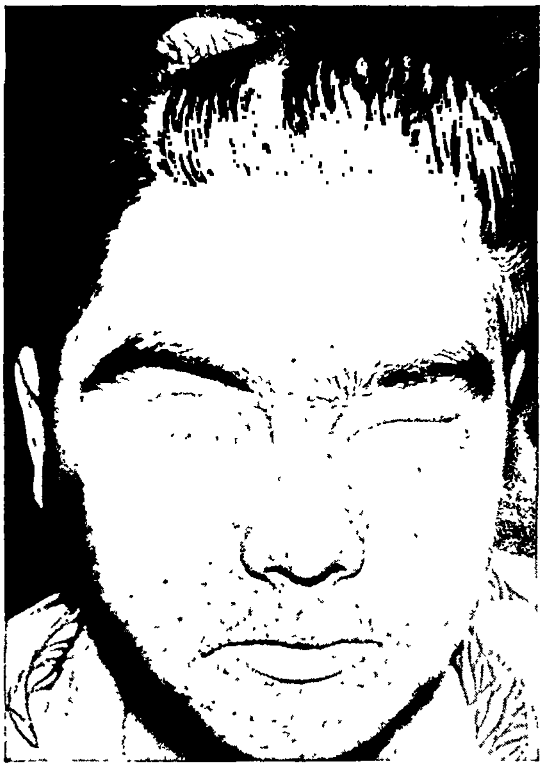

Fig. 5 (case 9).—Moon face and acne of Cushing's syndrome produced by pituitary adrenocorticotropic hormone, 100 to 150 mg daily for three weeks (angioendothelioma).

(*d*) *Altered Response to Infection.*—When the dose of either of the two drugs was reduced or stopped, several patients had fever, at which time evidence of pneumonia or other respiratory infection was first noted. A reinstitution of full doses of the drug has produced control of fever but not necessarily a disappearance of the infection. This sudden onset of evidence of infection occurred less frequently when withdrawal of the drug was gradual. It is possible that when the drug is withdrawn abruptly a temporary hypoadrenocortical state is produced. Another possible explanation is that therapy masks the infection, preventing the usual febrile reaction until withdrawal of the drugs.

(*e*) *Pigment Disturbances.*—Eleven of the patients given pituitary adrenocorticotropic hormone or cortisone displayed greatly increased pigmentation of the skin and darkening of moles while they were receiving the drugs. Two patients had pigmentation in the buccal mucosa, as seen in Addison's disease. The patient with melanoma had melanotic infiltration, absent before treatment, in an abdominal scar.

(*f*) *Sexual Disturbances.*—Amenorrhea developed in the two patients previously having regular periods. Both patients experienced vasomotor disturbances. Acne occurred in eight patients during pituitary adrenocorticotropic therapy and in two during cortisone therapy (fig. 5). Hirsutism occurred in seven of the female patients and in one preadolescent boy.

(*g*) *Cushing's Syndrome.*—Cushing's syndrome with remarkable changes in the face, fat deposits on the shoulder and neck, abdominal protrusion, acne and hirsutism occurred in three patients who received continuous or frequently repeated courses of therapy for five weeks, three months and six months, respectively. This disappeared gradually over a period of six weeks without therapy, but became an exceedingly distressing complication in one previously good-looking woman (fig. 6).

ANATOMIC CHANGES PRODUCED BY PITUITARY ADRENOCORTICOTROPIC THERAPY

Autopsies on six patients who had received pituitary adrenocorticotropic hormone showed that there had occurred a moderate hyperplasia of the adrenals (average weight 10.9 Gm.), a decrease in the size of the thyroid gland (average weight 18 Gm.) and degenerative changes of the female genitalia. The pituitary gland contained variable numbers of eosinophils, basophils and chromophobe cells, and no conclusion could be drawn. Crooke cells were not noted. All the patients had extensive pyogenic infection involving the skin, lungs or kidneys. The patients had the usual number of fibrous adhesions of the serous membranes and benign tumors. The structure of the latter did not appear to be altered by the hormone. Biopsies and specimens obtained at autopsy showed an increased number of macrophages containing melanin. Normal skin and lymphatic tissue did not appear to be affected by the drug.

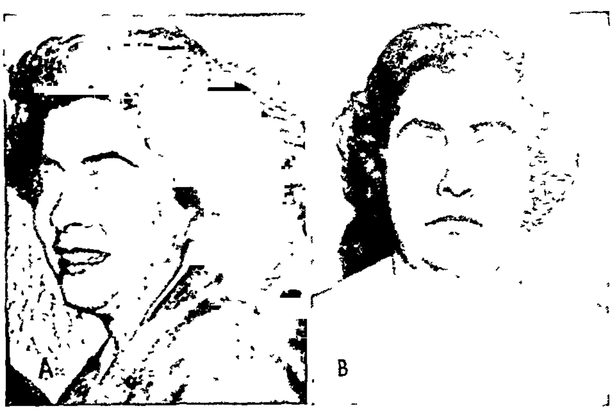

Fig. 6 (case 18).—Patient with advanced Hodgkin's disease (*A*) six months prior to cortisone therapy; *B*, Cushing's syndrome produced by 11.5 Gm. of cortisone given over a 90 day period. Note the fat pads on the shoulders and the moon face.

COMMENT

The nonspecific beneficial effect of pituitary adrenocorticotropic hormone and cortisone in patients not showing tumor regression is a phenomenon on which it is interesting to speculate. It may represent an inhibition of the local tissue reaction to the tumor, analogous to the inhibition of the tuberculin reaction produced in hyperimmune guinea pigs by cortisone, as reported by Stoerk.[10] Dramatic improvement in breathing occurred in a patient with carcinoma of the trachea; this has been repeatedly produced with decreased inflammatory reaction around the tumor and relief of bronchial spasm with courses of one or the other drug for the last 13 months, although the tumor itself has been progressing. Reduction in fever is characteristic in other diseases treated with the drugs.[11] This does not appear to be a typical antipyretic reaction, as it is not associated with sweating. This again may be related to inhibition of tissue reaction.

In only the patients with lymphosarcoma, chronic lymphatic leukemia and Hodgkin's disease does there appear to be any worth while benefit. However, most of these patients show improvement only when side effects become troublesome and at times alarming; they then relapse before complete recovery from these side effects has occurred, making further therapy impossible or unwise.

Only one patient with Hodgkin's disease has had a remission, lasting four months. This patient has Hodgkin's disease of the liver, the disease being of recent origin and previously untreated.

SUMMARY AND CONCLUSIONS

Twenty-six patients with advanced neoplastic disease have been treated with pituitary adrenocorticotropic hormone (ACTH) or cortisone. The former was given in doses of 100 to 200 mg. daily, for individual periods of two weeks to three and one-half months. The latter was given in doses of 100 to 300 mg. daily for similar periods.

Temporary regression of neoplastic lesions were produced in 3 patients with Hodgkin's disease, 5 patients with lymphosarcoma and 1 patient with chronic lymphatic leukemia. A doubtful regression of angioendothelioma (Ewing's sarcoma) occurred with pituitary adrenocorticotropic hormone.

Patients with carcinoma, acute leukemia, myelogenous leukemia and melanoma showed no control of the neoplastic disease, but most patients manifested striking temporary improvement in their general condition.

Physiological alterations produced by these hormones given in large doses make repeated or prolonged therapy ill advised.

Cerebral Hemorrhage and Cerebral Embolus.—The diagnosis of cerebral embolus is indicated whenever there is a sudden onset of neurologic symptoms in a patient with an acute or chronic endocarditis, auricular fibrillation, a recent coronary thrombosis, septicemia or a septic focus. These cases often present clinical evidence of embolic phenomena elsewhere in the body. The differential diagnosis between cerebral hemorrhage and thrombosis is difficult since both occur in patients of the same age group and in patients with arteriosclerosis and hypertension. Several points in the history and physical examination make this differentiation possible in the majority of the cases: 1. Convulsions at the onset favor an intracerebral hemorrhage since they occur in about 14 per cent of such cases and in only about 7 per cent of the patients with a cerebral thrombosis. 2. The occurrence of severe headache, nausea or vomiting at the onset favors the diagnosis of cerebral hemorrhage. 3. Cheyne-Stokes or labored respirations are much more common in cases of cerebral hemorrhage. The same is true of conjugate deviation of the eyes. 4. Stiffness of the neck, quadriplegia and bilateral Babinski's toe sign occur in a much higher percentage of the cases of cerebral hemorrhage. 5. A bloody cerebrospinal fluid is diagnostic of a cerebral hemorrhage.—*Proceedings First National Conference on Cardiovascular Diseases,* American Heart Association and The National Heart Institute, U. S. Public Health Service, 1950.

HOMOLOGOUS SERUM JAUNDICE

Report of Eight Fatal Cases

JOHN RUNYAN, M.D.
ARTHUR W. WRIGHT, M.D.
and
RICHARD T. BEEBE, M.D.
Albany, N. Y.

The occurrence of jaundice after the administration of human tissue products was first described by Hirsch,[1] who observed that jaundice developed in 14.8 per cent of 1,289 persons vaccinated for smallpox with "humanized lymph" in glycerin. A similar observation was made by Lürman [2] in 1885. By 1908 Weber [3] had collected from the literature 53 cases of acute yellow atrophy appearing in patients who had been treated in clinics for syphilis. Theiler [4] in 1918 observed jaundice in horses following the injection of homologous serum.

However, it was not until 1937 that the first report of the development of hepatitis after the injection of a preparation containing, among other substances, human blood serum appeared. In that year Findlay and MacCallum [5] reported the occurrence of hepatitis among British troops after yellow fever vaccination. Since this report hepatitis has been noted to result from the administration of convalescent measles serum [6] and mumps serum,[7] from immunization against sand fly fever [8] and from yellow fever vaccinations.[9]

The major impetus for the careful and detailed investigation of the cause of hepatitis following the introduction into the body of products containing human serum was provided by the report of 28,585 cases of hepatitis, with 62 deaths, occurring between Jan. 1 and July 4, 1942, among U. S. Army personnel who had been inoculated with yellow fever vaccine.[10] The extensive investigations of Sawyer and his co-workers [11] and earlier by Findlay and associates [12] definitely incriminated the human serum in the vaccine as the source of the icterogenic agent. The human serum component of the vaccine was eliminated after this outbreak.

The term homologous serum jaundice was first used in a memorandum prepared by medical officers of the British Ministry of Health in 1943.[6b] Hepatitis from both plasma and blood was mentioned at this time. Subsequent reports [13] would indicate that serum jaundice from whole blood was less common than from pooled plasma or serum. Spurling, Shone and Vaughn,[14] in a well controlled study, reported an incidence of 7.3 per cent of jaundice cases in 1,054 persons receiving serum or plasma but no definite cases in 891 others given a total of 2,278 transfusions of whole blood.

Bigger [15] in 1943 presented suggestive evidence that hepatitis may be spread by contaminated syringes. Outbreaks of jaundice have been reported in syphilitic,[16] diabetic [17] and arthritic clinics,[18] in a tuberculosis sanatorium [19] where monthly blood samples for sedimentation rates were taken, and after injections of penicillin [20] and acriflavine.[21] Cases of serum jaundice after thiopental (pentothal®) anesthesia have been mentioned.[20b] It has been shown [15] that staphylococci mixed with blood and sucked into a syringe were not completely removed or killed by repeated rinsing in sterile water and a biniodide antiseptic solution. Mendelssohn and Witts [22] demonstrated that some blood regurgitates back into the vein when venipuncture is done by the orthodox method, thus providing a means of transferring the agent present in a contaminated syringe into the blood of the subject. Various procedures have been suggested to eliminate these outbreaks, but the simplest is to use separate syringes sterilized by dry heat at 160 C. for one hour.[23]

Extensive study of the agent responsible for serum jaundice, as well as that of infectious hepatitis, has been handicapped by the inability to transmit the disease to animals.[24] Some hope for its successful transfer to birds, however, is found in the report of Lucké and Ratcliffe.[25] Homologous serum jaundice has been successfully transmitted to human beings by intradermal, subcutaneous, intramuscular and intravenous injections,[26] at least once by feeding serum [24a] and at least once by intranasal instillation.[24b] Transmission has been possible with a dose as small as 0.01 cc.,[27] and considering the dilution of the serum in the yellow fever vaccine [11] a yet smaller dose must have been effective.

The incitant of homologous serum jaundice, as well as that of infectious hepatitis, is filtrable,[28] is resistant to heating at 56 C. in the dried state for one-half hour,[24c] can be stored for months in the dried state [29] and for three and one-half years in the frozen state [30] and can be exposed for months to 0.5 per cent of an equal mixture of phenol and ether [29] and other bactericidal agents.[31] The serum hepatitis agent is present in the blood stream before jaundice becomes manifest [26b] and apparently disappears two to two and one-half months after jaundice clears.[24a, c] It has not been recovered from the stools.[32]

The incubation period, after introduction of the serum jaundice incitant, is variable, ranging from 40 to 180 days,[33] with a majority of the cases occurring 55 to 135 days after inoculation.[33b] Reinfection with the agent of serum hepatitis, called virus SH by Neefe, Gellis and Stokes,[30] has not been described, but there have been reports of reinfection with the incitant of infectious hepatitis, or virus IH,[34] although reinfection is unusual.[30] A previous attack of serum jaundice does not produce immunity against infectious hepatitis, and there is suggestive evidence that susceptibility is actually enhanced.[35] No cross immunity between serum hepatitis and infectious hepatitis has been demonstrated,[36] which is perhaps the best evidence that there are either two different agents or two immunologically distinct strains of the same agent.

Gamma globulin has proved to be of value prophylactically in infectious hepatitis by providing complete protection or by modifying the course of the disease.[37] Data on the use of gamma globulin in serum hepatitis are inconclusive. Grossman and co-workers [38] showed that two 10 cc. injections of gamma globulin given a month apart during the incubation period were highly protective among the victims of battle casualties. A single injection of 10 cc. prolonged the incubation period without altering the disease.[39] In human volunteer experiments gamma globulin neither protected against the strain of serum hepatitis virus used nor prolonged the incubation period.[40] Oliphant [24c] found that yellow fever vaccine containing the icterogenic agent, exposed to ultraviolet irradiation, failed to produce the disease when inoculated into 10 volunteers. Wolf and co-workers,[41] using an Oppenheimer-Levinson [42] apparatus, found that irradiation produced no significant alterations of the plasma protein levels. The

This article has been shortened in The Journal by omission of the footnotes, which will appear in the authors' reprints.

Drs. Lawrence J. Early of Hudson, N. Y., S. Gene Rogati of Valatie, N. Y., Sidney Kimelbolt of Castleton on Hudson, N. Y., and T. Frank Marnell of Great Barrington, Mass., permitted us to report the patients seen with them recent work of Blanchard and co-workers[43] with a Hakel and Sockrider type of apparatus,[44] suggests that irradiation of plasma and serum is both safe and highly effective in preventing serum hepatitis Inoculation of 11 volunteers with irradiated icterogenic serum failed to produce hepatitis, although it developed in 47 per cent of the control group Allergic responses were not observed with irradiated serum and plasma

With the increasing use of plasma and whole blood, the number of cases of homologous serum jaundice will continue to rise proportionately When one considers an incidence of 1 6 to 7 3 per cent,[45] with a mortality rate "considerably higher" than 0 2 to 0 4 per cent,[46] the importance of serum hepatitis cannot be underestimated That the use of pooled plasma which has not been irradiated and/or whole blood is not without danger is again brought out by the seven fatal cases here reported An eighth case is added, even though the patient received neither plasma nor whole blood, because the peculiar contact of the victim with one of the seven patients included in this report may represent an unusual mode of transmission of the icterogenic agent

REPORT OF CASES

CASE 1—J F, a white man aged 39, with a known duodenal ulcer, was admitted to the hospital on Sept 21, 1944 because of symptoms of obstruction and pain He underwent subtotal gastric resection a week later During the operation he was given 500 cc of whole blood and 250 cc of nonirradiated plasma His recovery was uneventful, and he was discharged

Forty five days after the operation an upper respiratory tract infection with fever developed This was followed by the appearance of light stools, dark urine and jaundice On the day of the patient's second admission, December 3 he had visual hallucinations and became confused He lapsed into a semicomatose state shortly before he was seen in the Emergency Room At this time his temperature was 95 2 F and his pulse was rapid and weak He was decidedly jaundiced and stuporous, and there was a cholemic odor to his breath The liver was not percussible The red blood cell count was 4 5 million per cubic millimeter, the hemoglobin was 15 Gm, the white blood cell count was 20 000, with 69 per cent neutrophils, 27 per cent lymphocytes and 4 per cent monocytes The urine showed bile (1 plus) and contained a few red blood cells The blood sugar was 35 mg and the nonprotein nitrogen 48 mg, per 100 cc The icterus index was 67 and the carbon dioxide-combining power 28 Lumbar puncture revealed nothing abnormal in either dynamics or chemical content The patient expired 24 hours after admission

At autopsy the body was moderately jaundiced The liver was much smaller than normal, weighing only 1,160 Gm Its capsule was thin, delicate and wrinkled slightly Through it the alternating dark reddish and paler grayish red, soft, flabby hepatic tissues could be seen The cut surfaces showed still more clearly the alternating dark and light reddish areas indicative of extensive acute degeneration and necrosis The appearance save for the atrophy and flabbiness, was not unlike the nutmeg appearance of chronic congestion The organ had the general flabby, dark red splotchy characteristics of red atrophy

Histologically the liver showed evidence of extensive, widespread acute hemorrhagic necrosis Every lobule was affected The hepatic cells were decidedly and diffusely reduced in number, and the bulk of the tissue of each lobule was severely diminished in amount In the spaces where the hepatic cells had been there now were present accumulations of macrophages, many filled with brown pigment, neutrophils and often erythrocytes Here and there, especially at the peripheral portions of the lobules degenerated or necrotic hepatic cells with their cytoplasm swollen, granular and finely vacuolated still persisted, either singly or in small groups They were usually so degenerate, and sometimes so large and filled with small vacuoles that it was difficult to recognize them There was no evidence of any attempts at regeneration Because of lobular shrinkage as a result of hepatic cell necrosis, the portal zones were much closer to each other than usual, presenting the appearance of the liver of acute yellow atrophy The portal areas, too were diffusely infiltrated with chronically inflamed cells, especially lymphocytes Intrahepatic bile ducts and ductules appeared to be increased in number, but this is interpreted as a relative increase only, for there was no evidence of actual proliferation of these structures The kidneys of this patient were large and pale and histologically showed the changes of advanced tubular nephrosis, the proximal convoluted tubules being most extensively involved

CASE 2—H C, a white man aged 20, underwent operative intervention shortly after admission on Oct 5, 1944 for an appendical abscess At operation he received 500 cc of whole blood and 250 cc of nonirradiated plasma The next day an additional 250 cc of plasma was given His postoperative course was uneventful, and he was discharged October 22

He remained well until Dec 14, 1944, 70 days after he received the plasma He then began to experience chills, fever and malaise, and jaundice developed On his admission to the hospital four days later he was acutely ill, semicomatose and jaundiced, with a temperature of 95 4 F There was tenderness in the right upper abdominal quadrant

His hemoglobin was 12 Gm The leukocyte count was 16,900 per cubic millimeter, the nonprotein nitrogen was 104 mg and the blood sugar 95 mg, per 100 cc, the icterus index was 58 and the serum bilirubin 8 7 mg per 100 cc The test for bile in the urine was positive, urobilinogen was normal He did not respond to parenterally given fluids and to oxygen therapy, he expired six hours after admission

At autopsy the skin surfaces were all decidedly icteric The liver was atrophic, weighing 1,460 Gm Its edges were soft, and the organ appeared browner than is normal Portions of the capsular surface were inflamed and covered with a thin layer of fibrinopurulent exudate The exposed cut surfaces of sections were mottled reddish gray, congested and soft, and the stromal markings were increased Each lobule seemed to be composed of a dark reddish center surrounded by a paler gray zone which appeared necrotic The appearance was characteristic of diffuse necrotizing hepatitis

Histologically the liver showed the same widespread, diffuse hemorrhagic necrosis as seen in case 1 but in an earlier stage All lobules were affected, but many hepatic cells, either in various stages of degeneration or already necrotic, were still recognizable Most of these were in the peripheral or middle zones of the lobules, the cells in the central portions being necrotic or missing Also present within the hepatic cords, mixed with persisting liver cells and sometimes actually surrounding or infiltrating them, were macrophages and neutrophils Many erythrocytes were also present, evidence of actual hemorrhage into the hepatic tissues No evidence of regeneration could be found Pigment deposits were relatively few and inconspicuous Portal areas were closer together than normal, were infiltrated with inflammatory cells and contained increased numbers of bile ducts The latter structures actually appeared to be proliferative, for their number and appearance suggested their regenerative character although actual mitoses were not observed The kidneys were large and pale, they showed the changes of advanced tubular nephrosis similar in type to that found in case 1

CASE 3—E C, a woman aged 40, a housewife, aborted spontaneously and hemorrhaged severely on Dec 17, 1944 During her three weeks' hospitalization she had several profuse hemorrhages and was given numerous plasma and whole blood transfusions A severe reaction followed the first blood transfusion, and it was found that she was Rh negative

On April 30, 1945 (103 days after the patient first received plasma and blood) she complained of restlessness and became lethargic Gradually she became comatose, progressive jaundice developed, and she was admitted to the hospital on May 2 She was in deep coma and was severely jaundiced Her temperature was 97 F The liver was felt 1 fingerbreadth below the costal margin The hemoglobin level was 16 Gm, and the leukocyte count was 10,300 per cubic millimeter The blood sugar level was 57 mg and the nonprotein nitrogen 120 mg, per 100 cc, the carbon dioxide-combining power was 34 volumes per cent

The total serum protein determination was 5.8 Gm., with albumin 2.4 Gm. and globulin 3.4 Gm., per 100 cc. The prothrombin time was 150 seconds. The icterus index was 51, the serum bilirubin was 8.8 mg., total cholesterol 106 mg., free cholesterol 50 mg. and cholesterol esters 56 mg., per 100 cc. The test for bile in the urine was positive. The patient died 24 hours after admission.

At autopsy the liver of this patient was extremely small, weighing only *1,000 Gm.* Its capsule was thin, transparent and smooth, and through it could be seen the pale but congested, soft flabby hepatic tissue. On sectioning the organ the cut surfaces were found to be paler than normal, central congestion alternated with lighter bands of yellowish gray, suggestive of fatty degeneration and necrosis. Histologically, the changes in the liver were those of acute massive necrosis affecting the central and midzonal regions of the lobules and tending to affect less severely the peripheral portions. Hepatic cells were missing in the central parts of the lobules, their places being taken by inflammatory cells, particularly macrophages, some with ingested light brown pigment. Lymphocytes and neutrophils were not abundant. At the periphery of the lobules, however, were periportal zones of persisting hepatic cells which showed advanced fatty degenerative changes. The degenerative cells sometimes occurred singly but were more often in small groups tending to surround the portal areas, which themselves were heavily infiltrated with lymphocytes. Intrahepatic bile ducts were not unduly prominent, and there was no evidence of regeneration of either hepatic cells or bile ducts. The kidneys, as in the other cases, were large, pale and soft and were the seat of advanced nephrotic changes which affected primarily the proximal convoluted tubules.

Case 4.—I. C., a white woman aged 18, after tonsillectomy in another hospital on Nov. 17, 1948 hemorrhaged profusely. She went into shock and was given 1,000 cc. of nonirradiated plasma. She had a slight chill after receiving the second unit of plasma, but she made an uneventful recovery.

She began to feel ill and to have a copper tint to her skin 67 days after receiving the plasma. A week later she was found in a coma by a physician who was called to see her. She was admitted to the hospital on Jan. 30, 1948, deeply jaundiced and in a comatose state. The liver was not enlarged. The blood sugar level was 57 mg. and the nonprotein nitrogen 48 mg., per 100 cc. The leukocyte count was 12,800 per cubic millimeter. Shortly after admission she began to have convulsions, which continued until her death 24 hours later. An autopsy was not obtained.

Case 5.—M. B., a white female infant 14 days of age, entered the hospital on Jan. 11, 1948 with a five day history of diarrhea. At this time she was acutely ill, with a temperature of 103 F., evidence of dehydration, grayish skin, and rales at both lung bases. Fluids were administered parenterally, and during the following two days small quantities of whole blood and nonirradiated plasma were given. The infant had an extremely stormy course, but she eventually recovered and was discharged 68 days after admission.

On May 8, which was 119 days after the child first received plasma and blood, she became restless and refused to eat. Vomiting followed, with evidence of abdominal pain and, later, the appearance of mild jaundice and chalklike stools. Vomiting became more profuse, and 12 days after the onset of symptoms the infant was readmitted. She appeared lethargic and moderately icteric, the temperature was 102 F. The liver was enlarged 2 fingerbreadths below the costal margin. Several convulsive seizures occurred and she grew rapidly worse, dying two hours after admission. Bilirubin was 9.6 mg. per 100 cc., and the cephalin flocculation determination was 4 plus. The urine contained bile (2 plus) but was negative for urobilinogen.

At autopsy the body was only faintly icteric. The liver appeared larger than normal, weighing 240 Gm., 50 to 60 Gm. heavier than the average weight for this age. Its capsule was smooth, glistening and a mottled yellowish brown. The organ was said to be rather firm. Cut surfaces of sections revealed large, reddish, meaty foci which oozed blood and had lost all characteristics of normal hepatic architecture. About these foci were irregular patches of pale yellowish, lobulated liver tissue which appeared degenerated or necrotic.

Histologically, the changes in the liver of this infant were those of diffuse, massive, acute degeneration and necrosis in an early stage of development. No lobules were spared. In the central regions the hepatic cells were necrotic or missing, while farther toward the peripheral portions hepatic cells showing advanced fatty degeneration were present in considerable numbers. Inflammatory cells, especially macrophages and neutrophils, were abundant though scattered, and even lymphocytes were *sometimes seen. The most intense inflammation was present* in the central portions of the lobules and in the portal areas which in this case were actively inflamed. Bile ducts were abundant and in a few areas were found to be actively regenerating. Regeneration of hepatic cells was not observed. The kidneys, as in the other cases, were enlarged and nephrotic.

Case 6.—B. M., a white female infant 10 days of age, was admitted on Feb. 9, 1948 with a three day history of diarrhea. The patient was acutely ill, dehydrated and in a state of mild acidosis. During her 46 days of hospitalization, besides the usual parenteral fluids, she was given six small infusions of nonirradiated plasma and three transfusions of whole blood without reactions. She was discharged apparently well.

On May 27, which was 105 days after the first administration of plasma and blood, the child became jaundiced. Three days later she reentered the hospital because of vomiting. At this time she was decidedly icteric and lethargic. The liver was enlarged 4 fingerbreadths below the costal margin. The blood bilirubin was 12.2 mg., the nonprotein nitrogen 72 mg. and the blood sugar 37 mg., per 100 cc. The cephalin flocculation reading was 4 plus. The patient died eight hours after admission.

At autopsy the liver was not atrophied or enlarged, weighing 176 Gm. Its surface was smooth, glistening, yellowish brown and firm. The cut surfaces of sections had an irregularly mottled appearance and small, reddish, "meatlike" foci which oozed blood alternating with pale yellowish foci. The former were regions of so called red atrophy, while the latter were composed of degenerated hepatic tissues.

Histologically, the liver changes resembled those in the previous cases, namely, widespread, diffuse acute degeneration and necrosis. The necrosis was present particularly in the central portions of the lobules while degenerative changes, particularly of the fatty type, were noted chiefly in the peripherally situated cells that were filled with small vacuoles. Lobules generally were somewhat smaller than normal, and portal areas appeared closer together than normal. Macrophages, many of them filled with light yellow granules, and neutrophils were abundant, the latter cells chiefly in and about portal areas. Bile ducts were fairly numerous, but no evidence of regeneration of either hepatic cells or bile duct epithelium was found. The kidneys, as in all the other cases, were large, pale, and nephrotic.

Case 7.—T. F., a white man aged 61, 90 days prior to admission received numerous blood transfusions after he underwent resection of the lower part of the colon for benign polyposis in a Boston hospital. Jaundice appeared one week before his admission here on Oct. 22, 1948 and increased rapidly. The patient became semicomatose, his temperature was 99.1 and he was deeply jaundiced. The lungs were clear. The liver was not palpable. The urine was positive for bile. The hemoglobin was 15 Gm. The leukocyte count was 19,700 per cubic millimeter. The icterus index was 150, and the direct van den Bergh reading 5.5 mg. per 100 cc. The patient was given fluids intravenously, but he remained comatose and died 24 hours after admission. An autopsy was not obtained.

Case 8.—C. B., a woman aged 30, an undertaker's wife, was seen in consultation by one of us (R. T. B.) on June 13, 1949. A week previously she had displayed malaise and low grade fever followed by deepening jaundice, coma and convulsions. It was learned that she had assisted her husband in embalming the body of the patient I. C. (case 4) 128 days prior to her illness. Also, 68 days before her illness began she had a benign tumor removed from her right axillary region while under intravenous thiopental sodium anesthesia. However, adequate sterile technic is carried out routinely in the hospital where this latter procedure was done.

The patient was in coma, decidedly jaundiced, dehydrated and breathing rapidly. There were a few scattered coarse rales throughout both lung fields. The heart was not enlarged. The liver was not palpable. There was slight edema over both lower extremities. In spite of parenterally given fluids and aureomycin hydrochloride, she grew steadily worse and died 72 hours later. The urine contained albumin (3 plus) and the hemoglobin was 14.5 Gm. The leukocytes numbered 6,100 per cubic millimeter. The icterus index varied from 170 to 220.

At autopsy the liver was decidedly shrunken and weighed only 630 Gm. The capsule was yellowish green, and the cut surface was deep red. Sections revealed almost complete obliteration of parenchymal cells with proliferation of the bile ducts. There was engorgement of the sinusoids with red cells and many macrophages, some of which contained yellowish brown pigment. The kidneys showed the changes of advanced nephrosis.

COMMENT

The striking characteristics of these eight cases of acute hepatitis, all but one of them occurring in patients who had received either plasma and/or whole blood from 45 to 128 days before the onset of symptoms, are the acute, fulminant nature of the illness and the fact that it progressed speedily to death within a few days. In general, the clinical course of the disease in the eight cases was similar and the duration of illness, from onset to death, was from three days in case 1 to 13 days in case 3. There was a predominance of central nervous system symptoms with psychosis (case 1), convulsions and varying states of consciousness. According to the classification outlined by Turner and co-workers,[9b] these could be grouped under subdivision one.

The precise incubation period cannot be definitely established in these cases with the exception of cases 1 and 4, because the blood or plasma was given over a period of several days or longer. The shortest possible incubation period was 45 days, the longest 128 days. These periods fall well within the reported extreme variable, but the fatal outcome would seem to bear no particular relationship to the length of the incubation period.

Five of the patients in this series received whole blood and nonirradiated plasma; the other two received either blood alone or plasma alone. The source of the icterogenic agent in case 8 is not definitely known. The development of serum hepatitis in three laboratory assistants and three orderlies handling contaminated serum has been described,[47] as well as hepatitis occurring in a blood bank worker who had received multiple needle pricks on the fingers.[19] It is quite possible that accidental inoculation took place when the body of I. C. (case 4) was embalmed. The long incubation period (128 days) is in the range of that found in serum hepatitis. Although hepatitis following intravenously given thiopental sodium is known to occur,[20b] adequate sterile technic is used in the operating rooms of the hospital where the benign tumor was removed, and it is less probable that inoculation took place at this time.

It is remarkable that six of the eight patients included in this report came to autopsy. We have been able to find in the literature [48] only scattered reports of the autopsy observations in cases of serum hepatitis. Lucké in his classic description of fatal infectious hepatitis [49] did not attempt to separate cases due to contact infection from those due to infection from blood, serum or products containing serum or its derivatives. Undoubtedly many of his cases were due to inoculation of patients with virus in blood, plasma or serum.[50] From gross and microscopic points of view, the pathologic changes in the livers of these patients were similar to, if not actually identical with, the findings reported in Lucké's monograph.

In general the liver was smaller than normal, although in at least two cases the organ was normal in size or slightly enlarged. Its surfaces were generally smooth, though sometimes wrinkled, and the color was mottled reddish and yellow or yellowish gray. The organ was generally flabby and sometimes quite soft. When sections were examined the changes of diffuse necrosis, sometimes hemorrhagic in type, were evident. The organ was sometimes bile stained, sometimes not.

The histologic changes were those of widespread acute degeneration and necrosis. In the case in which death occurred only a few days after onset, degenerative changes and necrosis of the hepatic cells predominated; in those in which death did not occur for a week or more, necrosis was advanced and many hepatic cells had already been removed, leaving only stroma and inflammatory cells. In none of the cases was any normal hepatic tissue found. Degeneration, necrosis or actual cell lysis and removal affected all the hepatic tissues.

Actual regeneration of hepatic cells and bile duct epithelium was noted only rarely in these cases, possibly because of the rapid progress of the infection to death. The histologic picture was that of an overwhelming, fulminating, hepatic-cell-destroying process which progressed rapidly to a point where all liver tissues were either degenerated or destroyed.

There is suggestive evidence that serum hepatitis from pooled plasma may be prevented by the use of ultraviolet irradiation.[51] The routine use of irradiated plasma was instituted in the Albany Hospital in February 1949. Since then there have been 10 known cases of hepatitis that have followed the administration of irradiated plasma and whole blood. This group will be reported in detail elsewhere.

As multiple injections with a single syringe and venipuncture using improperly sterilized syringes may spread the agent of serum hepatitis, these practices are not without danger. It is to be stressed that the hazards of serum hepatitis exist not only for recipients of human blood products but also for laboratory workers, technicians, nurses, physicians and undertakers.

SUMMARY

1. Seven cases of fatal serum hepatitis from whole blood and/or pooled plasma are reported, with autopsy observations in 5. An eighth case of fatal hepatitis in which blood or plasma had not been administered, also with autopsy, is added because the circumstances strongly suggest that the infection was contracted while the woman helped to embalm a person who died of serum hepatitis. Ten additional cases are mentioned in which the patients had received irradiated plasma and whole blood.

2. The pathologic changes found at autopsy in the liver and kidneys of six patients who died are described in some detail.

3. Further clinical evaluation of ultraviolet-irradiated plasma in the prevention of serum hepatitis will be necessary before final conclusions can be drawn.

4. Efforts should be made to avoid the use of a single syringe for multiple injections and the use of improperly sterilized syringes for venipuncture.

5. The potential dangers of serum hepatitis for laboratory workers, technicians, nurses, physicians and undertakers are not to be minimized, and precautions against self inoculation should be taken.

HOMOLOGOUS SERUM JAUNDICE AND ITS RELATION TO METHODS OF PLASMA STORAGE

The infective agent responsible for homologous serum jaundice or serum hepatitis is thought to be a virus. It is transmitted by transfusion or inoculation in man by human products, particularly by blood, plasma or serum, but it has not been successfully transmitted to other species. The disease has been produced in human volunteers by as little as 0.1 cc. of infected plasma.[1] For this reason, one donor who is a carrier of the disease can infect an entire pool of plasma. It has been recommended that the donor population of pooled plasma not exceed five and that plasma be used only as an emergency measure. As a consequence, plasma is not used as extensively as before. This hazard of pooled plasma must be overcome if it is to be stockpiled and used for civilian defense.

The purpose of this report is twofold first, to call attention to the fact that the current and generally employed methods for the storage of plasma are highly favorable to the preservation of viruses; second, to present data indicating that when plasma is stored in the liquid state without preservatives at temperatures ranging between 80 and 96 F. for three months or longer, homologous serum jaundice is infrequently encountered if indeed it occurs at all Plasma stored in this manner for 18 to 24 months appears as effective for nutritive purposes as when stored for six months or less.

METHODS OF VIRUS PRESERVATION

The principal methods employed for the preservation of viruses are lyophilization, storage at dry ice or deep-freeze temperatures (— 70 to — 20 C), refrigeration (— 4 to + 4 C.) and storage in glycerin. According to Topley and Wilson[2]: "Most viruses appear to be very resistant to cold. Frozen and dried they may live for many months. Survival in distilled water, saline or Ringer's solution varies considerably. In the ice box many viruses will survive a long time, but most of them perish rapidly if kept at room temperature or 37 C." Augmenting this point of view are data we obtained from a survey of the literature on survival characteristics of 33 virus agents pathogenic for man. In every instance in which information was available, lyophilization, freezing and refrigeration favored prolonged virus survival. Storage at room temperature, on the other hand, resulted in loss of activity in a few hours to a few days even though the agent may remain virulent in the lyophilized or frozen state for months to several years.

Lyophilization, deep freezing and refrigeration, which are the best means of preserving virus activity, are also widely employed for the storage of human plasma. This may account for the persistent incidence of homologous jaundice (5 to 10 per cent) which follows transfusion of pooled plasma. A survey of the methods of plasma storage used by a number of observers reporting homologous serum jaundice following plasma transfusion discloses that in every instance the pathogenic product was stored under conditions favorable for the preservation of virus activity. Of historic and practical interest in this connection is the first reported epidemic of serum hepatitis which occurred in the Bremen shipyards in 1883. Vaccination for smallpox with human lymph stored in glycerin resulted in latent icterus in 191 of 1,293 persons treated.[3]

A review of the literature available to us discloses that homologous serum jaundice has been reported[4] from plasma or serum preserved as shown on table 1. It is clearly evident from this table and from the literature pertaining to the survival qualities of other viruses that if the blood product is to be stored in the lyophilized, frozen or refrigerated states it must first be free of all virus contaminants. Failing this, these products must be stored for an undetermined period of time under some condition which is unfavorable for virus preserva-

the winter seasons are regularly 78 to 82 F. The temperature is more variable during the seasons of late spring, summer and early autumn, when the room temperature is a function of the weather. In the interest of economy of space, representative daily room temperature readings are not included. Storage of plasma under these conditions was originally begun because refrigeration facilities were not available when our blood bank was started in 1942. This practice has been continued because it has proved satisfactory.

TABLE 3.—*Age Distribution of Plasma Transfused*

Age in Days	Units Transfused	Age in Days	Units Transfused	Age in Days	Units Transfused	Age in Days	Units Transfused

85-94	362	275-334	262	755-934	36	....	...

From Sept. 1, 1942 to June 1, 1950, a total of 864 patients received 6,502 of the 9,406 units of blood from which 356 pools of plasma were made. Samples from all these pools have been administered, although some units until recently were discarded after the one year arbitrary expiration date. Many of these patients received plasma from several pools and were thus exposed to a fairly large donor population. The average donor population of each pool was 26. Each patient received, on the average, plasma from 44 donors because generally more than one unit of plasma was given, and often these units were from different pools.

From the beginning of our blood bank, an attempt was made to restrict the administration of any pool of plasma until it had aged two to three months, in order that some deterioration in isoagglutinin titer might occur. Except when clinical demands were great, this was usually possible. Table 3 records the ages of all the various units of plasma at the time of administration.

An analysis of the end results of plasma transfusion with reference to the occurrence of homologous serum jaundice had to be the subject of search of each patient's clinical record, as no patients with this complication from our plasma had come to the attention of either the attending service or the blood bank. This record search was extended to include also most of those patients who had received only blood. Thirteen of the

time the survey was made. The charts of the 864 patients who received plasma were reviewed later for a second time. The length of the follow-up period for each patient was tabulated, and these data are presented in table 4.

The over-all incidence of homologous serum jaundice for pooled plasma is reported by various workers as between 2.4 and 12 per cent of the patients transfused. Perhaps the most reliable estimate made in this country is the careful survey of Brightman and Korns[4j] in which at least 29 of 649 patients receiving war surplus lyophilized plasma were considered to have contracted the disease. The incidence of the disease is much higher (23 to 100 per cent) when computed on the basis of the patients receiving units from any one infected pool (table 1).

A number of possible mathematical means may be employed for estimating the number of patients receiving our plasma in whom homologous serum jaundice could be expected to develop, but none is without the criticism that the data would be handled with some arbitrary advantage. The basic facts in our data are: first, 23,320 whole blood transfusions were given to 6,503 patients; second, 9,406 plasmas were pooled into 356 pools, so that each final plasma unit contained on the average 26 donors. Of this plasma, 6,502 units were given to 864 patients, who on the average received plasma from 44 donors based on an analysis of the individual's plasma transfusion record as the plasma was actually given. Of this latter group, 212 patients did not receive blood in connection with their plasma therapy. The homologous serum jaundice syndrome appeared in 14 patients receiving blood alone. Three more patients, given both blood and our plasma, also exhibited this syndrome, although in each of these three patients it seemed unlikely that our plasma was the cause of their infection. None of the 212 patients who received our plasma *alone* were known to have manifested the disease.

CASE 7.—P. S., a man aged 70 with a squamous cell carcinoma of the skin, underwent operative intervention on Dec. 2, 1944, and 600 cc. of blood was given at that time. Two other blood transfusions were given, one on December 18 and one on December 26. On May 1, 1945 the patient had symptoms of hepatitis with mild icterus and lack of appetite; he required three weeks' hospitalization. Complete recovery was made. A history of previous hepatitis was not elicited from the donors. Plasma was not given.

CASE 8.—E. M., a woman aged 50, was admitted with a diagnosis of Hodgkin's disease on Jan. 31, 1947. One blood transfusion was given March 13, and the patient was discharged March 16, 1947. Jaundice was first noted July 28, 1947, preceded by anorexia of ten days. No treatment of Hodgkin's disease was actively conducted for three months before the onset of jaundice. The jaundice receded and disappeared with restoration of appetite by August 14. The patient made a recovery from hepatitis and is still alive. Plasma was not given.

CASE 9.—H. B., a man aged 72, was given three blood transfusions for anemia, one on Nov. 5, 1946, the second on November 19 and the third on December 17. Onset of hepatitis with icterus occurred March 5, 1947. The patient recovered after three weeks. Subsequently one blood donor gave a history of jaundice three months before giving blood for this patient. Plasma was not administered.

CASE 10.—A. C., a woman aged 53, her condition diagnosed as Hodgkin's disease, was given blood transfusions on January 15, 17, 18 and 21 in 1949. She was readmitted to the hospital March 14, 1949 with jaundice, nausea and vomiting. She was given a course of nitrogen mustard therapy totaling 28.8 mg., started March 30. She continued to go downhill, although jaundice cleared. She expired on April 7, 1949. Plasma was not given. Liver sections showed a decided increase of portal fibrous tissue without extension to form lobular divisions. Only occasionally was Hodgkin's disease in evidence. Leukocytes and round cell infiltration were present in most areas.

CASE 11.—R. W., a man aged 60, was admitted Nov. 21, 1947 with pyogenic arthritis. Blood transfusions were given November 26, and December 6, 9 and 11. On March 8, 1948, the urine darkened and there developed nausea, lack of appetite and jaundice. This gradually cleared up over four weeks' time, and the patient was well as of April 19, 1950. Plasma was not given.

CASE 12.—F. H., a man aged 64, with a diagnosis of carcinoma of the descending colon, underwent operation on Dec. 16, 1948 and received two units of blood. His convalescence was uneventful, and he was discharged on the twelfth day. He was readmitted May 8, 1949 with onset of anorexia, nausea, vomiting and jaundice of three days' duration. Needle biopsy of the liver was compatible with hepatitis; the diagnosis was presumed to be homologous serum jaundice. The patient improved, and he was discharged at the end of two weeks and is well at present. He did not receive plasma.

CASE 13.—E. G., a woman aged 47, with a diagnosis of chronic lymphatic leukemia, received five blood transfusions between Sept. 15 and Dec. 20, 1949. Anorexia, nausea and icterus developed on Jan. 28, 1950. Donors were interrogated but without revealing any possible source of infection. Her course in the hospital was uneventful and her recovery from hepatitis was complete. During this hospital stay she did not receive antileukemic therapy. Plasma was not given.

CASE 14.—L. G., a woman aged 60, with a diagnosis of carcinoids of small intestine, received five blood transfusions beginning on October 4 and ending November 7, 1949. No plasma was given. On Jan. 15, 1950 the patient developed anorexia, nausea and vomiting, and within a day or two, jaundice appeared which subsided spontaneously over a period of three to four weeks. Interrogation of the blood donors disclosed no evidence of previous hepatitis.

CASE 15.—J. S., a man aged 60, was admitted with a diagnosis of duodenal ulcer. He received three blood transfusions Dec. 15, 1947 in the treatment of an acute episode of gastrointestinal bleeding presumed to be from a duodenal ulcer. No plasma was given. He was admitted for surgery on March 15, 1948 and, on the day surgery was planned, icterus was noted. Aside from jaundice, the patient was otherwise asymptomatic. Jaundice cleared in three weeks. No surgery was performed. Investigation of the donors did not disclose the source of infection.

CASE 16.—E. F., a woman aged 60, was admitted March 19, 1950 with a diagnosis of hypernephroma of the left kidney, an adenoma malignum of the descending colon and diabetes mellitus. On March 27 the left kidney was removed and a local resection of the descending colon was performed. She received one 500 cc. blood transfusion March 22 and two blood transfusions of 500 cc. each March 27 during operation. Her recovery was uneventful, and she was discharged April 9. She was readmitted May 6, 1950 complaining of anorexia, nausea, generalized pruritus and jaundice of three to ten days' duration. A diagnosis of homologous serum jaundice was made, and conformation of hepatitis was obtained by needle biopsy of the liver. Jaundice subsided, and she was discharged May 18, 1950. The three donors were recalled, but no history of hepatitis or jaundice was obtained. Plasma was not given.

CASE 17.—V. S., a woman aged 33, on June 21, 1950 had a cesarean hysterectomy with right salpingo-oophorectomy. Her course was complicated by pelvic vein thrombosis. She received one 500 cc. blood transfusion on the day of surgical intervention. Her recovery was otherwise uneventful, and she was discharged July 6 in good condition. She was readmitted on July 25, 1950 with complaints of epigastric distress, anorexia, nausea and vomiting of less than one week's duration. Homologous serum jaundice was suspected, and the diagnosis of hepatitis was confirmed by needle biopsy. Her course improved and jaundice disappeared by August 12. She was discharged on Aug. 15, 1950. She did not receive plasma. On requestioning the donor, no history of hepatitis or jaundice was obtained.

PLASMA TRANSFUSION

Save for the three patients whose clinical summaries are presented in case reports 1, 2 and 3, we have not encountered any other patients receiving our plasma who are known to have had the homologous serum jaundice syndrome. Although our plasma cannot be completely excluded as the cause of infection in these three patients, it seems more likely that whole blood or lyophilized plasma was the icterogenic agent concerned. In support of this contention are the important facts that in none of the other 39 patients receiving the remaining plasma units from these pools did there develop recognizable latent hepatitis or icterus and that at least one blood donor to each of these three patients gave a history of previous hepatitis and jaundice.

Because of the relatively large number of patients transfused, 6,503 with blood alone and 864 with our plasma with or without blood, we believe that we should have encountered some definite evidence of transmission of the disease by our plasma unless the unusual means of its storage influenced the virulence of the virus. The method of our plasma preparation from the beginning of the Blood Bank, Sept. 15, 1942, has been the same and is as follows:

> Plasma is prepared from outdated blood (five days or older). It is separated from the sedimented red cell mass and thereafter stored at room temperature until used. Each blood transfusion is drawn into a 75 cc. aqueous solution of sodium citrate (2 Gm.) and is stored at refrigeration temperatures (4 to 8 C.) until transfused as such or converted into plasma, pooling generally with plasma from 25 to 30 other donors. After five days all bloods are made into plasma. This plasma is stored at room temperature without preservatives.

The temperature of the room in which the plasma is stored is higher than might be expected, as the liquid plasma is stored within 2 feet of the ceiling and is in the same room where blood bank equipment is autoclaved. In addition, a 30 gallon steam still also is located there and is in continuous operation 12 hours a day, six days a week. Temperatures recorded during tion. If the latter procedure is followed, the method of storage must not destroy the activity of the product as far as its therapeutic value is concerned.

HOMOLOGOUS SERUM JAUNDICE AT THE UNIVERSITY OF CHICAGO CLINICS

BLOOD TRANSFUSION

As the members of the medical profession became generally aware of the possibility that delayed jaundice after transfusion was due to the transmission of a virus contained in the transfused human product, they began to make the diagnosis of homologous serum jaundice in patients in whom there developed latent icterus after transfusion. During the past eight years 33 of our patients have returned with jaundice and this diagnosis has been made. Sixteen of this group had either a previously established primary liver disorder or metastatic liver tumor and are therefore excluded from this series unless biopsy or autopsy evidence of hepatitis could be established. None of these 16 patients had received our University of Chicago plasma. The remaining 17 patients are considered as having acquired the disease, and their cases are reported below and summarized in table 2.

Plasma only	1,356	44	0	212
Blood and plasma	Blood 3,332 Plasma 5,066	Blood 4.8 Plasma 48	3	652

CASE 1.—A. C., a man aged 47, had chondrosarcoma of the ilium and bleeding duodenal ulcer. He was admitted Jan. 15, 1950 and was transfused with four units (1,000 cc.) of our plasma on the same day. This was from two separate pools. The ages of these pools were 145 days and 182 days at the time of administration. The total donor population of these two pools was 60. Thereafter the patient was given whole blood, 2,000, 1,000, 3,000 and 2,000 cc., respectively, on January 16, 17, 19 and 20, on which day a subtotal gastrectomy was performed. Subsequent transfusions were as follows: 3,250, 500, 500 and 500 cc. on January 21, 26, 28 and 31, respectively. He was discharged in good condition February 19 and readmitted March 26, 1950 with nausea, vomiting and anorexia accompanied with jaundice of three days' duration. Diagnosis of homologous serum jaundice was made, and he recovered. In all he had received blood transfusions from 39 donors and four units of our plasma. Requestioning of donors used for blood transfusion disclosed that two of them had had symptoms of jaundice. The remaining units of these plasma pools were given, in one instance to 17 patients as 250 cc. units and in the second case to eight patients as 500 cc. units. These patients were reexamined but no evidence of jaundice or symptoms of hepatitis developed, although two had died within less than two months of other disease.

CASE 2.—M. A., a woman aged 48, was admitted with a diagnosis of ulcerative colitis. In 1948 she received blood transfusions on March 5, 23, 24, 25 and 31, April 1, 2, 3, 4 and 20, May 17 and 25 and June 20 and 22. She received one 500 cc. transfusion of our plasma on March 24 with a donor population of 34 donors. The age of this plasma unit was 143 days. Thereafter she was given war surplus lyophilized plasma on March 25, 26, 27, 28, 29, 30 and 31, April 1, 2, 3, 4 and 5 and 1,200 cc. on April 6 and 7. On August 21 symptoms of hepatitis began. Jaundice was noted the following day. The patient became oliguric but began to improve September 1, although icterus was present until September 16. She was discharged on her forty-third hospital day (October 10) and has remained well since. In all, 11,000 cc. of lyophilized plasma were given. The remaining units of our plasma pool were given to nine patients who were followed for six months but in whom symptoms of hepatitis or jaundice did not develop; one other patient receiving this plasma died two weeks later of other disease.

CASE 3.—J. M., a man aged 19, whose diagnosis was trabecular reticulum cell sarcoma of the left iliofemoral chain of glands, had an operation for excision of this chain of glands with resection of external iliac and proximal portions of superficial and deep femoral veins on June 22, 1949. During the operation he received four transfusions of whole blood and four units of our plasma from two different pools whose combined donor population was 55. The ages of the plasma units were 215 and 392 days. An additional 500 cc. blood transfusion was given July 5, and recovery was uneventful. The patient was discharged on August 20 and readmitted October 12 with a 10 day history of jaundice, anorexia, nausea and some vomiting. This slowly improved over a period of three weeks. Two needle biopsies of the liver were done and showed severe hepatitis. One performed October 15 and a second performed October 29 disclosed considerable improvement since the first examination. One of three blood donors who were recontacted gave a history of jaundice 40 years before. The other two donors did not return. The remainder of each plasma pool was administered as 500 cc. units to six patients and eight patients, respectively, in none of whom symptoms of hepatitis had developed within a six month follow-up period.

CASE 4.—K. H., a woman aged 82, was first admitted to Billings Hospital in November 1948 and was found to have a gastric ulcer. Subtotal gastrectomy was done Dec. 8, 1948. She received two whole blood transfusions preoperatively, one on November 27 and one November 28. On February 1 jaundice developed. This progressed until the death of the patient. Necropsy disclosed evidence of hepatitis.

CASE 5.—F. S., a patient aged 64, was admitted January 2, 1950 with carcinoma of rectum and sigmoid with intestinal obstruction. A combined abdominal-perineal resection was done and three transfusions totaling 1,650 cc. of blood were given. Three blood transfusions were also given January 5, 12 and 26 during the postoperative period. On March 10 the patient manifested painless jaundice with acholic stools and anorexia but without fever. This subsided after three weeks, and since then the patient has been well. Plasma was not given.

CASE 6.—C. J., a man aged 64, underwent operation for pyogenic arthritis of two joints on April 29, 1944. Two days prior to operation, one transfusion of whole blood was given. Four weeks later a transurethral resection was done because of benign prostatic hypertrophy. Seventy-two days after the transfusion the man was readmitted because of headache and dizziness. Two days later he became comatose, bleeding from the nose and intestinal tract; he died on the third hospital day. At autopsy the liver weighed 1,300 Gm. and was yellow with increased prominence of globular markings. Microscopic examination revealed fine granular fat dispersed throughout the entire liver section with nearly complete destruction of the lobular architecture, except in the periportal areas where abortive attempt at regeneration was evident. Numerous round cell infiltrations were evident throughout the liver lobules and periportal areas. The blood donor was requestioned, but no history of hepatitis could be elicited. Plasma was not given.

CASE 7.—P. S., a man aged 70 with a squamous cell carcinoma of the skin, underwent operative intervention on Dec. 2, 1944, and 600 cc. of blood was given at that time. Two other blood transfusions were given, one on December 18 and one on December 26. On May 1, 1945 the patient had symptoms of hepatitis with mild icterus and lack of appetite; he required three weeks' hospitalization. Complete recovery was made. A history of previous hepatitis was not elicited from the donors. Plasma was not given.

CASE 8.—E. M., a woman aged 50, was admitted with a diagnosis of Hodgkin's disease on Jan. 31, 1947. One blood transfusion was given March 13, and the patient was discharged March 16, 1947. Jaundice was first noted July 28, 1947, preceded by anorexia of ten days. No treatment of Hodgkin's disease was actively conducted for three months before the onset of jaundice. The jaundice receded and disappeared with restoration of appetite by August 14. The patient made a recovery from hepatitis and is still alive. Plasma was not given.

CASE 9.—H. B., a man aged 72, was given three blood transfusions for anemia, one on Nov. 5, 1946, the second on November 19 and the third on December 17. Onset of hepatitis with icterus occurred March 5, 1947. The patient recovered after three weeks. Subsequently one blood donor gave a history of jaundice three months before giving blood for this patient. Plasma was not administered.

CASE 10.—A. C., a woman aged 53, her condition diagnosed as Hodgkin's disease, was given blood transfusions on January 15, 17, 18 and 21 in 1949. She was readmitted to the hospital March 14, 1949 with jaundice, nausea and vomiting. She was given a course of nitrogen mustard therapy totaling 28.8 mg., started March 30. She continued to go downhill, although jaundice cleared. She expired on April 7, 1949. Plasma was not given. Liver sections showed a decided increase of portal fibrous tissue without extension to form lobular divisions. Only occasionally was Hodgkin's disease in evidence. Leukocytes and round cell infiltration were present in most areas.

CASE 11.—R. W., a man aged 60, was admitted Nov. 21, 1947 with pyogenic arthritis. Blood transfusions were given November 26, and December 6, 9 and 11. On March 8, 1948, the urine darkened and there developed nausea, lack of appetite and jaundice. This gradually cleared up over four weeks' time, and the patient was well as of April 19, 1950. Plasma was not given.

CASE 12.—F. H., a man aged 64, with a diagnosis of carcinoma of the descending colon, underwent operation on Dec. 16, 1948 and received two units of blood. His convalescence was uneventful, and he was discharged on the twelfth day. He was readmitted May 8, 1949 with onset of anorexia, nausea, vomiting and jaundice of three days' duration. Needle biopsy of the liver was compatible with hepatitis; the diagnosis was presumed to be homologous serum jaundice. The patient improved, and he was discharged at the end of two weeks and is well at present. He did not receive plasma.

CASE 13.—E. G., a woman aged 47, with a diagnosis of chronic lymphatic leukemia, received five blood transfusions between Sept. 15 and Dec. 20, 1949. Anorexia, nausea and icterus developed on Jan. 28, 1950. Donors were interrogated but without revealing any possible source of infection. Her course in the hospital was uneventful and her recovery from hepatitis was complete. During this hospital stay she did not receive antileukemic therapy. Plasma was not given.

CASE 14.—L. G., a woman aged 60, with a diagnosis of carcinoids of small intestine, received five blood transfusions beginning on October 4 and ending November 7, 1949. No plasma was given. On Jan. 15, 1950 the patient developed anorexia, nausea and vomiting, and within a day or two, jaundice appeared which subsided spontaneously over a period of three to four weeks. Interrogation of the blood donors disclosed no evidence of previous hepatitis.

CASE 15.—J. S., a man aged 60, was admitted with a diagnosis of duodenal ulcer. He received three blood transfusions Dec. 15, 1947 in the treatment of an acute episode of gastrointestinal bleeding presumed to be from a duodenal ulcer. No plasma was given. He was admitted for surgery on March 15, 1948 and, on the day surgery was planned, icterus was noted. Aside from jaundice, the patient was otherwise asymptomatic. Jaundice cleared in three weeks. No surgery was performed. Investigation of the donors did not disclose the source of infection.

CASE 16.—E. F., a woman aged 60, was admitted March 19, 1950 with a diagnosis of hypernephroma of the left kidney, an adenoma malignum of the descending colon and diabetes mellitus. On March 27 the left kidney was removed and a local resection of the descending colon was performed. She received one 500 cc. blood transfusion March 22 and two blood transfusions of 500 cc. each March 27 during operation. Her recovery was uneventful, and she was discharged April 9. She was readmitted May 6, 1950 complaining of anorexia, nausea, generalized pruritus and jaundice of three to ten days' duration. A diagnosis of homologous serum jaundice was made, and conformation of hepatitis was obtained by needle biopsy of the liver. Jaundice subsided, and she was discharged May 18, 1950. The three donors were recalled, but no history of hepatitis or jaundice was obtained. Plasma was not given.

CASE 17.—V. S., a woman aged 33, on June 21, 1950 had a cesarean hysterectomy with right salpingo-oophorectomy. Her course was complicated by pelvic vein thrombosis. She received one 500 cc. blood transfusion on the day of surgical intervention. Her recovery was otherwise uneventful, and she was discharged July 6 in good condition. She was readmitted on July 25, 1950 with complaints of epigastric distress, anorexia, nausea and vomiting of less than one week's duration. Homologous serum jaundice was suspected, and the diagnosis of hepatitis was confirmed by needle biopsy. Her course improved and jaundice disappeared by August 12. She was discharged on Aug. 15, 1950. She did not receive plasma. On requestioning the donor, no history of hepatitis or jaundice was obtained.

PLASMA TRANSFUSION

Save for the three patients whose clinical summaries are presented in case reports 1, 2 and 3, we have not encountered any other patients receiving our plasma who are known to have had the homologous serum jaundice syndrome. Although our plasma cannot be completely excluded as the cause of infection in these three patients, it seems more likely that whole blood or lyophilized plasma was the icterogenic agent concerned. In support of this contention are the important facts that in none of the other 39 patients receiving the remaining plasma units from these pools did there develop recognizable latent hepatitis or icterus and that at least one blood donor to each of these three patients gave a history of previous hepatitis and jaundice.

Because of the relatively large number of patients transfused, 6,503 with blood alone and 864 with our plasma with or without blood, we believe that we should have encountered some definite evidence of transmission of the disease by our plasma unless the unusual means of its storage influenced the virulence of the virus. The method of our plasma preparation from the beginning of the Blood Bank, Sept. 15, 1942, has been the same and is as follows:

> Plasma is prepared from outdated blood (five days or older). It is separated from the sedimented red cell mass and thereafter stored at room temperature until used. Each blood transfusion is drawn into a 75 cc. aqueous solution of sodium citrate (2 Gm.) and is stored at refrigeration temperatures (4 to 8 C.) until transfused as such or converted into plasma, pooling generally with plasma from 25 to 30 other donors. After five days all bloods are made into plasma. This plasma is stored at room temperature without preservatives.

The temperature of the room in which the plasma is stored is higher than might be expected, as the liquid plasma is stored within 2 feet of the ceiling and is in the same room where blood bank equipment is autoclaved. In addition, a 30 gallon steam still also is located there and is in continuous operation 12 hours a day, six days a week. Temperatures recorded during the winter seasons are regularly 78 to 82 F. The temperature is more variable during the seasons of late spring, summer and early autumn, when the room temperature is a function of the weather. In the interest of economy of space, representative daily room temperature readings are not included. Storage of plasma under these conditions was originally begun because refrigeration facilities were not available when our blood bank was started in 1942. This practice has been continued because it has proved satisfactory.

TABLE 3.—*Age Distribution of Plasma Transfused*

Age in Days	Units Transfused	Age in Days	Units Transfused	Age in Days	Units Transfused	Age in Days	Units Transfused
35-44	10	95-124	650	335-394	378	935-1,054	14
45-54	60	125-154	703	395-454	230	1,055-1,174	4
55-64	170	155-184	778	455-514	90	Not recorded	80
65-74	250	185-214	712	515-574	74	Total	6,502
75-84	[illegible]	215-274	1,130	575-754	114	....	...
85-94	262	275-334	262	755-934	36	....	...

From Sept. 1, 1942 to June 1, 1950, a total of 864 patients received 6,502 of the 9,406 units of blood from which 356 pools of plasma were made. Samples from all these pools have been administered, although some units until recently were discarded after the one year arbitrary expiration date. Many of these patients received plasma from several pools and were thus exposed to a fairly large donor population. The average donor population of each pool was 26. Each patient received, on the average, plasma from 44 donors because generally more than one unit of plasma was given, and often these units were from different pools.

From the beginning of our blood bank, an attempt was made to restrict the administration of any pool of plasma until it had aged two to three months, in order that some deterioration in isoagglutinin titer might occur. Except when clinical demands were great, this was usually possible. Table 3 records the ages of all the various units of plasma at the time of administration.

An analysis of the end results of plasma transfusion with reference to the occurrence of homologous serum jaundice had to be the subject of search of each patient's clinical record, as no patients with this complication from our plasma had come to the attention of either the attending service or the blood bank. This record search was extended to include also most of those patients who had received only blood. Thirteen of the 14 patients receiving blood only had been called to our attention by the attending service. Only one patient (case 11) was brought to light by the record search.

TABLE 4.—*Number of Records of Patients Receiving Transfusions That Were Reviewed and Duration of Follow-Up*

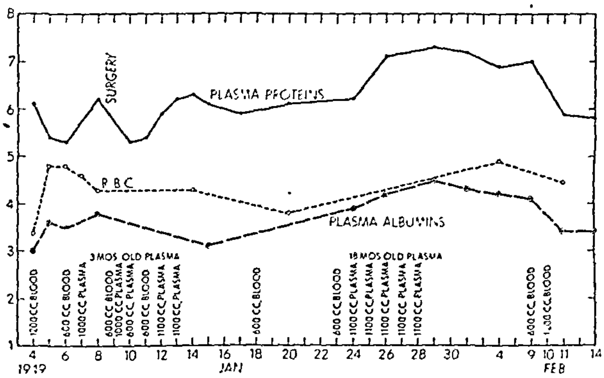
	1 Mo.*	1 Mo.	2 Mo.	3 Mo.	4 Mo.	5 Mo.	6 Mo.†
Blood only							
No. of records............	508	840	452	285	233	458	2,790
Percentage of total......	9.1%	15.1%	8.1%	5.1%	4.2%	8.2%	50.1%
Blood and/or plasma							
No. of records............	71	36	53	54	73	97	480
Percentage of total......	8.2%	4.2%	6.1%	6.3%	8.4%	11.2%	55.6%

* Died or followed less than 30 days. † Six months or longer.

Of 7,367 patients transfused with blood and/or our plasma, 5,566 records of patients receiving only blood were reviewed. All the charts of the 864 patients receiving our plasma were reviewed. Nine hundred and thirty-seven charts were either in active clinic use or had been microfilmed and were not available at the time the survey was made. The charts of the 864 patients who received plasma were reviewed later for a second time. The length of the follow-up period for each patient was tabulated, and these data are presented in table 4.

The over-all incidence of homologous serum jaundice for pooled plasma is reported by various workers as between 2.4 and 12 per cent of the patients transfused. Perhaps the most reliable estimate made in this country is the careful survey of Brightman and Korns [41] in which at least 29 of 649 patients receiving war surplus lyophilized plasma were considered to have contracted the disease. The incidence of the disease is much higher (23 to 100 per cent) when computed on the basis of the patients receiving units from any one infected pool (table 1).

A number of possible mathematical means may be employed for estimating the number of patients receiving our plasma in whom homologous serum jaundice could be expected to develop, but none is without the criticism that the data would be handled with some arbitrary advantage. The basic facts in our data are: *first, 23,320 whole blood transfusions were given to* 6,503 patients; second, 9,406 plasmas were pooled into 356 pools, so that each final plasma unit contained on the average 26 donors. Of this plasma, 6,502 units were given to 864 patients, who on the average received plasma from 44 donors based on an analysis of the individual's plasma transfusion record as the plasma was actually given. Of this latter group, 212 patients did not receive blood in connection with their plasma therapy. The homologous serum jaundice syndrome appeared in 14 patients receiving blood alone. Three more patients, given both blood and our plasma, also exhibited this syndrome, although in each of these three patients it seemed unlikely that our plasma was the cause of their infection. None of the 212 patients who received our plasma alone were known to have manifested the disease.



Response of plasma protein concentration to administration of plasma stored 18 months at room temperature, unit 460129. Protein level is shown in grams per 100 cc., red blood cells in millions per cubic millimeter.

NUTRITIVE VALUE OF PLASMA STORED AT ROOM TEMPERATURE

Because plasma is slowly metabolized it is the most valuable and effective means available for providing the patient with parenteral protein.[5] The accompanying illustration presents data which shows the capacity of plasma to elevate the plasma protein concentration after it has been stored 18 months to two years at room temperature in the liquid state. In two other instances this plasma was the only plasma administered, and similar responses in plasma protein concentration were achieved. Metabolic studies were performed and satisfactory positive nitrogen balances were obtained. The plasma protein responses were essentially the same as reported in previous studies from this laboratory, in which the plasma administered had been stored at room temperature for three to twelve months before use.[6]

COMMENT

To one who is cognizant that lyophilizing, freezing and refrigeration are the best means available for the preservation of virus activity, it is not surprising that when these same procedures are employed in the preservation of plasma the activity of the virus of homologous serum jaundice should also be preserved. The question arises, however, if this is true why are other virus diseases not transmitted under these same conditions? The answer probably lies in certain characteristics almost unique with the virus of homologous serum jaundice. Most other viruses pathogenic for man are present in the blood stream only a few days, and during this time the person is ill and therefore does not give blood. The virus of homologous serum jaundice, however, can be present in the blood stream for many weeks and at a time when the person is in apparently good health; hence, these persons are not rejected as donors.

Another pertinent problem concerns the known ability of the virus of homologous serum jaundice to resist various forms of physical exposure. For example, it is known that this virus will resist temperature of 56 to 60 C. for at least 30 minutes; that it will survive temperatures of 4 C. for long periods of time and temperatures of — 10 to — 70 C. for one to two and a half years.[7] At room temperature, but in the lyophilized state, the virus maintains its activity for at least a year.[10] It also survives in serum, refrigerated or frozen, with or without thimerosal (merthiolate®) concentrations of 1 : 1,000 to 1 : 2,000 with equal parts of phenol, and it maintains its activity in 0.5 per cent ether and in 0.2 per cent concentrations of tricresol at similar temperatures.[7] It is inactivated by exposure to ultraviolet light and heating at 60 C. for 10 hours. This virus is one of the most stable and resistant of all known viruses.

With these points of view in mind, is it possible that the virus of homologous serum jaundice can be inactivated simply by prolonged storage in a liquid cell-free state, in a temperature environment of the type employed in this report? According to Havens[7] the virus may remain virulent in the lyophilized state for one to four and a half years but becomes inactive after five years. Undoubtedly, if the virus will "die out" after prolonged storage under conditions favorable to virus activity, it will "die out" more rapidly under less favorable conditions. Our data suggest that the virus of homologous serum jaundice does not remain pathogenic in liquid cell-free plasma at temperatures ranging between 78 and 96 F. for more than three months. However, if this is true, the data do not tell us the minimum temperature or storage period at which this apparent inactivation occurs.

Since this study rests entirely on data obtained from a record search and from complaints of previously transfused patients, it is open to the criticism that a personal inquiry into the subsequent course of each patient with reference to possible latent homologous serum jaundice was not made. Undoubtedly, some patients were missed in a project of this magnitude. On the other hand, 14 patients who received only blood, five days old or less, manifested a syndrome that seemed compatible with homologous serum jaundice. Since nearly one fourth of all of our blood was converted into plasma, each pool containing on the average the blood of 26 donors and the average patient receiving a total plasma donor population of 44, it is evident that we could expect some homologous serum jaundice to develop from plasma. This does not appear to have happened. These observations differ from those of all other investigators "who have found the incidence of hepatitis following pooled plasma transfusion many times greater than following transfusion of blood."[4g]

There is no reason to suspect that the patients who received our plasma were immune to homologous serum jaundice, or, for that matter, immunized against a return to our clinic to an extent greater than were those who received our whole blood. The only logical conclusion is that the susceptibility to homologous serum jaundice from our plasma was less than that from our whole blood. As far as we know, this is the only report in which the incidence of homologous serum jaundice following plasma transfusion was less than that following blood transfusion.

Although it is reasonably certain that the 17 patients whose cases are reported herein had hepatitis with jaundice, it cannot be stated that in every instance the jaundice and hepatitis were transmitted by blood. The possibility of sporadic or endemic infectious hepatitis as the primary cause of their disease cannot be excluded. It is not yet possible to distinguish accurately between homologous serum jaundice and endemic hepatitis in patients who have received parenteral human products. However, since all the previous reports also are open to the same criticism, we believe that this objection has no special significance in connection with our data.

It appears likely that the incidence of homologous serum jaundice as indicated by our record search is a minimum figure, for undoubtedly some of our patients in whom latent icterus developed were treated elsewhere or failed to report for medical attention at all. It must be borne in mind in estimating the incidence of any infectious disease that the results obtained are measured in terms of the resistance of the host and the virulence of the organism. The absence or low incidence of the disease in patients receiving our plasma was probably the result of a reduced virulence of the organism rather than an increased resistance on the part of the patient, since the disease did occur following transfusions of whole blood. No evident case selections were in function to determine which patients should receive blood and which should receive plasma. It is our belief that if storage of liquid plasma at relatively high room temperatures for at least two to three months does not cause the death of the virus its virulence is reduced to the extent that few if any patients receiving such plasma manifest the disease.

"Sterilization" of plasma or serum containing viruses may be accomplished by a number of methods besides prolonged storage of the liquid cell-free product at room temperature. Chief among these are exposure to ultraviolet light, certain ionizing radiations and chemical agents, especially nitrogen mustard. Until all the factors concerning the toxicity and the safety of this practice are known, its use beyond that of clinical investigation should not be encouraged. The use of plasma irradiated with ultraviolet light has not completely eradicated the problem of homologous serum jaundice. This may be corrected when the light energies necessary to kill the virus without impairing the physiologic value of the plasma are known and such information employed as routine procedure. Objections of similar nature apply to the prolonged storage of liquid plasma at high room temperature, because neither the optimal temperature or minimal storage period for inactivation of the virus are established. Our data do not prove that room temperature storage under the conditions we report actually kills the virus, but if it does not the resistance qualities of the virus of homologous serum jaundice would be unique in this respect. For these reasons, we do not contend that the prolonged room temperature storage of liquid plasma should be generally practiced as a means of preventing homologous serum jaundice at present, although our data suggest that this *is a simple and safe method for reducing or abolishing* the incidence of homologous serum jaundice from pooled plasma.

In the past eight years this plasma has been successfully employed in the emergency treatment of shock. Precise comparison with plasma stored under other conditions is not possible from our experience, but we have no clinical observations to indicate that our plasma is unsatisfactory in this respect. The criticism that plasma stored at room temperature could be a means for the transmission of bacterial contaminants is, in our opinion, not justified. It is true that plasma or serum stored under these conditions is an ideal culture medium for many organisms. In our experience, when bacterial contamination occurs one or more of several phenomena are readily noticeable: the plasma becomes turbid and may develop a flocculum; it may coagulate and often is rapidly discolored, and if gas is formed by the organism the stopper is frequently blown off the bottle. Contaminated plasmas can generally be recognized and set aside even before the routine culture data from the bacteriologic laboratory have been reported.

Liquid proteins generally are denatured on prolonged storage at room temperature. It is inconceivable that plasma as we have stored it does not undergo some changes of this sort. Nevertheless, such changes as may occur do not appear to impair the nutritive capacity of such plasma. On no occasions did the three patients receiving 18 to 24 months old plasma exhibit any untoward reaction. In all, 81 units of "old" plasma were administered to these three patients. The over-all reaction in our clinic to blood transfusion is 2.8 per cent compared to 0.4 per cent for our plasma.

A study of the physical and chemical qualities of liquid plasma stored at room temperature from three months to eight years is in progress and will be the subject of a later report.

SUMMARY

1. Lyophilization, freezing and refrigeration, almost exclusively employed in the preservation of plasma, are also the most suitable means available for the preservation of virus activity. As long as these methods are employed for the storage of plasma, it is imperative that pooled plasma be sterilized in some manner before such storage procedures are instituted in order to reduce or obviate the troublesome incidence of homologous serum jaundice from pooled plasma.

2. No virus is known to survive prolonged room temperature in a cell-free liquid state without preservatives. In the University of Chicago Clinics, where plasma has been stored at high room temperature for a period of three to 12 months before use, it appears doubtful that any patient has contracted homologous serum jaundice from this plasma. Of 864 patients given units of our pooled plasma stored in the liquid state at 78 to 96 F. for three months or longer, three are known to have contracted homologous serum jaundice. The source of infection in these three patients seemed more likely due to the blood received by two of them or to the lyophilized plasma or blood given the third patient. None of the 212 patients who received our plasma alone was known to have had latent jaundice. This plasma appears undiminished in its nutritive value and is remarkably free of elements causing untoward reactions.

3. During the same period, at least 14 and probably 16 or 17 of 6,503 patients receiving only refrigerated whole blood transfusions manifested latent jaundice typical of the homologous serum jaundice syndrome. Case abstracts of these 17 patients are reported.

OCCURRENCE OF HEPATITIS IN RECENTLY TATTOOED SERVICE PERSONNEL

BALLARD F. SMITH, M.D.
Buffalo

I shall attempt to demonstrate in this paper a possible relationship between tattooing and hepatitis. A perusal of the literature up to June of 1949 failed to reveal any mention of the subject of tattooing in hepatitis, hence, a report at this time is all the more pertinent. In the absence of the actual reproduction of the disease in human volunteers with material from a suspected reservoir, positive proof can never be offered and all conclusions must be based on deduction, elimination and supposition. All the data were obtained from the medical service of Fort Clayton Hospital, Fort Clayton, Canal Zone, where enlisted patients of the three services were observed. Results of the study thus far on the subject of tattooing and hepatitis have been considered of sufficient weight already to warrant preventive measures against another possible mode of dissemination of hepatitis, just as hospital technic has been altered in the past five years to prevent transfer of the hepatitis virus through supplies, not only in blood products but also in needles.[1]

SERUM HEPATITIS AND INFECTIOUS HEPATITIS

The etiological agent in the two forms of homologous serum jaundice, infectious hepatitis and serum hepatitis, is as yet unidentified. Electron microscopic examinations of filtered extracts of proved infected serum have disclosed nothing. Implantation on the chick embryo has produced no consistent or reproducible lesions.[2] Inclusion bodies have not been found by the pathologist in studies of patients with hepatitis.[2] However, because of the ability of the etiological agent to pass through bacteria-retaining filters, it would seem that the name virus would be most applicable to the causative agent.

Presently located at the Veterans Administration Hospital, Buffalo.

Read before the Medical Association of the Isthmian Canal Zone, May 16, 1950.

With the assistance of Col. W. D. Graham, commanding officer, Fort Clayton Hospital, and Lieut. Col. Norman Elton, chief, Board of Health Laboratory, Gorgas Hospital, Ancon, Canal Zone.

[2] Hepatitis, Combined Staff Clinics, Am. J. Med. **4:** 285, 1948.

Considerable experimental work has been done in an attempt to prove or disprove the theory that the viruses in infectious and serum hepatitis are one and the same. In support of the theory it is stated that the etiological agents are equally elusive, filtrable and resistant, as well as productive of identical changes in vivo. Aycock and Oren[3] showed that by giving the virus of infectious hepatitis parenterally to 22 volunteers a prolonged incubation period resulted, averaging 61.6 days. They deduced that this tended to substantiate a common cause for both diseases. They went on to state that the probable cause for the longer incubation period of serum hepatitis was either partial inactivation of the virus by human serum or inoculation of virus from a convalescent or abortive case. Neefe and his co-workers,[4] doing original work, and Haggard,[5] expertly summarizing the experimental work, have forcibly contended that a different agent is causative in these two diseases. Their conclusions are based on the fact that cross immunity does not exist between the two kinds of hepatitis. This has been well established not only in experimental infections but also in the numerous large wartime series of cases.

Actually, the only differences between the two diseases are the mode of transmission and the incubation period. Serum hepatitis is transmitted parenterally with a 40 to 160 day incubation period and infectious hepatitis orally with a 15 to 40 day incubation period. Clinically, there is no symptomatic, laboratory or duration difference that may be applied to the individual case.[6] When differences in the two diseases have been found, there have been other factors, such as the older age in serum hepatitis in the peacetime series or the battle wounds which were a concomitant in many other wartime series. The lack of ability to differentiate has been true of the cases which will be discussed in this paper.

Probably the most significant factor about the viruses of hepatitis which has fostered perpetuation of the disease has been their extreme hardiness in the presence of measures which usually are effective in eradicating bacterial disease. Environmental extremes are not deleterious to the viruses, as they survive several years in the frozen state and at least a year when desiccated at room temperature.[7] A high level of resistance to thimerosal (merthiolate®), equal parts of phenol and ether, alcohol and a temperature of 56 C. for 30 to 60 minutes has been shown. One of the few practical effective measures for destroying the virus in blood products is irradiation with ultraviolet light for 45 minutes at 2,537 angstrom units.[8] Boiling for 30 minutes is effective but only applicable in instrument sterilization.

TATTOOING AS MODE OF TRANSMISSION

The impetus of this investigation came about in July 1949 when it was noted on making rounds on the enlisted male medical ward that the most decorative section seemed to be the one reserved for patients with hepatitis. On closer scrutiny the reason became apparent. The tattooed males were predominant in this section. Many of these patients had been tattooed within two to five months prior to onset of symptoms, and this cutaneous glorification had been performed most commonly at the same establishment in Panama City.

Twenty-six cases of hepatitis were followed in this series. All patients were included who had hepatitis occurring after January 1949 and could be called back for further questioning or who came into the hospital after the study began. The patients were asked whether, when and where they were tattooed. They were questioned about past history of jaundice or contact with jaundiced persons, whether they had been hospitalized within the past six months and, most important, whether they had received any blood transfusions or plasma within the past year. Because of the time elapsing between the tattooing and the symptoms, often the incubation period was approximated to the nearest week.

It was found that 18 of the 26 men, or 69 per cent, had been tattooed 49 to 154 days prior to the onset of their symptoms. All tattoos which were done outside the 40 to 160 days were not considered as a possible cause of the serum hepatitis. Three of the patients had had more than one tattoo. Each had had at least one tattoo within the incubation period. All 18 patients denied contact with any jaundiced persons. Seventeen of the 18 had been tattooed at the same establishment. Two had been tattooed the same night at the same place and entered the hospital during the same week for therapy. They knew of no other likely contact, mutual or otherwise. In these two patients the clinical courses were quite different, one being much more deeply jaundiced and thereby requiring protracted hospitalization. In another patient who was hospitalized for a fractured nose hepatitis developed in the fourth week of his hospitalization. He gave a history of being tattooed 65 days prior to symptoms. The average time elapsing between tattooing and symptoms in the 18 patients was 99 days.

All the patients were returned to duty within three months with no evidence of impaired liver function. Each was checked one month after discharge, and only one patient required rehospitalization. No clinical or laboratory difference was evident between the 18 patients with significant tattoos and the other eight patients.

Because the incidence of tattooing is known to be high among service personnel, hospitalized enlisted men were questioned on this subject at three separate times until a total of 200 cases were obtained. The only patients excluded were the hepatitis patients in the hospital at these times. Sixty-one patients (30 per cent) were found to have had tattoos. Sixteen (8 per cent) of these patients had been tattooed at the establishment previously mentioned. None of these 16 gave a history of jaundice, but two had hepatomegaly; however, both had normal hepatic function tests. This comparison in tattoos in the nonhepatitis series of 30 per cent and total tattoos in the hepatitis series of 88 per cent seems to constitute a significant difference.[9]

9. In the series of 26 cases were 18 patients with significant tattoos and 4 who were tattooed outside of the average incubation period of serum hepatitis.

The next step taken was to study the tattooing methods locally used and to ascertain whether the technics might be conducive to virus propagation. The procedure disclosed was as follows: The skin was shaved and washed with alcohol and allowed to dry. Then the stencil of choice was dusted with fingerprint powder and applied to the skin. After removal of the stencil the pattern was "needled in" with from two to four colors. The colors were kept in separate containers. All transfer to the patient from the container was by direct "dips" of the tattoo needles. A tattoo needle consists of a battery of four or five needles in a row, attached to a vibrator. A separate needle battery was used for each color. When the material at the end of the first dip had been used up on the skin, the needle was redipped into the dye container. The process was continued until the pattern was completed. Between customers, the needle was wiped with a cotton rag and dipped into a 3 ounce (90 cc.) alcohol bottle and allowed to dry. When the dye in the working container became depleted more dye was added from the stock bottle. The alcohol bottle likewise was replenished frequently from a larger stock bottle.

It would be a simple matter to harbor the viable virus of serum hepatitis both in the dye container and in the alcohol bottle for a long period of time under these favorable conditions. The tattooer stated that his work was not satisfactory unless he "drew blood" with the needles. Blood and serum were therefore directly introduced into the dye containers, and it would seem possible that one customer who was a carrier could contaminate all dye containers and the alcohol container as well. That this is possible is further supported by the small amount of serum necessary to transfer the virus, 0.001 cc. according to Scheinburg.[10] Sawyer and others[11] have suggested that as high as 6 per cent of the population are periodic carriers. They based their results on tracing the infected donors in pooled plasma.

CONTROL MEASURES

Certain control measures were put into effect after the preliminary report of suspected tattoo-spread hepatitis in Panama City and Colon. On Feb. 8, 1950 all tattoo operations were ordered suspended until the tattooists could be instructed in a safe way to operate. More acceptable technic was explained to the three operators on the Pacific side and the one on the Atlantic side. Two of the establishments reopened on the Pacific side and one on the Atlantic side, with the following modus operandi. Individual containers of dye are used for each customer. These are boiled for at least 30 minutes before reuse. Dye for each case is transferred from central containers to an individual container with a tongue depressor, which is used only once. Each needle is boiled for 30 minutes before reuse. One needle battery is used instead of the four which were used previously. This technic would seem adequate, provided it is religiously followed, to prevent the transfer of serum from one customer to another.

CONCLUSIONS AND SUMMARY

1. Serum hepatitis and infectious hepatitis remain entities by virtue of differences in their epidemiology and incubation period.

2. Twenty-six cases of hepatitis were analyzed for a possible common source of infection. Eighteen (69 per cent) of the patients were found to have been tattooed in Panama City within 49 to 154 days prior to the onset of their symptoms. Seventeen of these 18 men had been tattooed at one place. This incubation period is compatible with the incubation period of serum hepatitis.

3. Among routine hospital admissions in a series of 200 patients, 30 per cent were found to have been tattooed, but only 8 per cent were tattooed in Panama City (comparing identicals) and none of these were tattooed within the incubation period of serum hepatitis. Among the 26 hepatitis patients, 88 per cent had been tattooed in Panama City and 69 per cent within the incubation period of serum hepatitis. The possibility is offered that tattooing is an important mode of transmission of hepatitis among service personnel. 4. The tattooing technics were investigated and found to be such that viable virus of serum hepatitis could be transferred from one customer to the next. Corrected technics, if adhered to, should prevent tattoo-needle inoculation.

ADVANCES IN THE MANAGEMENT OF JAUNDICE

Experiences with 500 Jaundiced Patients

FREDERICK STEIGMANN, M.D.
Chicago

The jaundiced patient presents a peculiar problem for treatment inasmuch as the icterus itself, although only a symptom of some underlying disease, produces certain physiological disturbances which have to be considered in the treatment of the patient. Moreover, regardless of the underlying condition causing the jaundice, which must be kept in mind during the planning of the treatment, the factor of liver changes must be considered in the adequate care of the icteric patient. It is presently acknowledged that whether the jaundice is due to a hepatitis (virus or toxic) or whether it is due to some disease process in the extrahepatic biliary tract, there is an impairment of the liver parenchyma. The damage, however, is of variable degree. Severe icterus brings with it a number of changes within the liver itself and within the digestive tract, which must be appreciated when therapy is planned. In treating patients with jaundice one must follow a definite plan which should include all the various factors that directly or indirectly may affect the various functions of the hepatobiliary tract.

In general, the treatment of jaundice has for its objective the removal or destruction of the causative factor, the amelioration of symptoms, the prevention of further damage and the repair of already damaged tissues at the earliest time and by the simplest mode, in order to prevent profound changes which may lead to scars and severe impairment of function.

The above objectives have been considered in the therapeutic regimen of over 500 jaundiced patients during the past five years. These patients included all types of jaundice and presented variable degrees of liver damage. The youngest patient was 10 years

of age and the oldest 76. The group was composed of both white and Negro, male and female patients. Some of these were seen during the acute (first) attack of jaundice and some during recurrent episodes. After discharge from the hospital many of them were followed in the outpatient clinic so that their later course could be observed.

This paper is based on the experiences gained from the therapeutic results in the above group of patients. In it are presented the various therapeutic procedures employed in this group. It should be stressed that not all the procedures were applicable in all patients and that some procedures have been used only on an exceedingly limited scale because they were only recently added to the therapeutic armamentarium. With these exceptions in mind, the following therapeutic plan is presented and some of the underlying basic principles are discussed.

REST

Regardless of the type of jaundice, it is advisable that the icteric patient be put to bed and kept there until the course of the disease or the etiologic basis is well established. Some types of jaundice (for example, those due to liver damage, particularly of the virus nature) are extremely sensitive to physical exertion.[1] Hence, bed rest as complete as possible in given circumstances should be instituted. Bed rest prevents jarring and massage of the liver, and it may also prevent the excessive metabolism of other tissues which usually occurs during exercise. Some of the products of excessive metabolism, if not toxic to the liver per se, have to be detoxified by the liver, thus increasing the work of a damaged organ and possibly resulting in greater impairment. There is sufficient available evidence to support the need for strict bed rest particularly during the acute and convalescent phases of hepatitic icterus.

DIET

Since in most instances there is as yet no specific treatment for liver disease, and since it has been found that certain dietary substances are important in the production or in the prevention of liver damage,[2] it is obvious that the diet is of utmost importance in patients with jaundice. Nevertheless there are certain controversial points concerning the dietary management of such patients. Essentially there is agreement that all patients with jaundice should have a high caloric, high vitamin, high carbohydrate and high protein diet.

Fats.—The amount of fat in the diet is somewhat controversial. Some believe that the fat content should be low,[3] others that it should be average[4] and some that it should be high[5] in order to give the patient a high caloric, palatable diet. My observations indicate that in patients with acute jaundice the fat content plays a comparatively minor role and that it is immaterial whether the fat content is average, slightly above or slightly below the average. I like to give these patients a high caloric diet so prepared that they consume it all. If a little more fat will make the diet more palatable there is no objection to giving more fat. In patients with the chronic type of jaundice (particularly cirrhosis) I believe that the amount of fat should be small (average or less than average) because in these patients less fat is better handled from the point of view of both absorption and transportation. Fats of animal origin (excluding dairy fats) with their high content of unsaturated fatty acids are particularly injurious, increasingly so after heating.[6]

Fats are necessary for building up a high caloric diet. Second, diets without fats are not palatable and are poorly taken. Third, fats contain all the fat-soluble vitamins which are also necessary in body metabolism.

Because of these factors a certain amount of fat is a necessary constituent of any diet which has to be used for any length of time. The amount of fats ingested, however, must be regulated in certain patients with jaundice. Small quantities of fats should be given to those who have either poor digestion or poor absorption of fats as evidenced by steatorrhea or in whom the turnover of fat is pathologic and in whom the intake of even average amounts of fat may lead to increased fat deposits in the liver. Since it is agreed that a fatty liver is a "sick" liver, one which is more susceptible to injury from endogenous and exogenous hepatotoxins,[7] it is apparent that in order to protect the liver one should prevent excess deposition of fat in it. Obviously in the acute stages of jaundice which last for a short time the degree of fat absorption and fat retention plays a minor role. In the patients with chronic jaundice, however, in whom there is danger of increasing the already pathologic fat stores in the liver, the amount of fat may have to be curtailed, sometimes drastically.

Carbohydrates.—For many years diets high in carbohydrates have been advocated for patients with jaundice. This has continued until the present day. Patients with jaundice do require a carbohydrate intake anywhere from 350 to 500 Gm. daily, depending on the size of the person. If this amount of carbohydrate cannot be given by mouth, part of it may have to be given by a parenteral route. It is important to watch for glycosuria in order to be able to control it if it should occur. This control can take the form of more frequent feedings with smaller amounts of carbohydrates or in rare instances the administration of small doses of insulin to help in the metabolism of the ingested carbohydrate. The carbohydrates which are easily digested and of low residue are preferable for jaundiced patients.

Proteins.—Not until the late 1930's was the importance of proteins in jaundice recognized. Prior to that era a diet low in protein was the treatment of choice for such patients. In the past decade, however, a diet high in protein of high "biologic value" has become the accepted treatment for jaundiced patients, not only because proteins are needed for rebuilding damaged tissues but also because they contain many amino acids which are essential for normal metabolism of the liver. The value of the various individual amino acids for certain specific metabolic functions of the body is continuously being recognized. Furthermore, the products of some of these proteins are of great importance for the normal function of endocrine and exocrine glands, the secretions of which in turn influence liver metabolism. The experiences with nutritional deficiencies of some prisoners of war during World War II have demonstrated the significant changes that may occur in the body economy, such as body fluid, hormonal secretions and immunity, from an insufficient supply of protein. Proteins are greatly needed not only by patients with liver disease but also by those with jaundice of extrahepatic origin who have to undergo surgical intervention, because hypoproteinemia interferes with prompt and adequate wound healing.

VITAMIN SUPPLEMENTS

Patients with jaundice should receive additional vitamin supplements despite a diet which is high in calories and vitamins. Usually additions of all vitamins are necessary.

Fat-Soluble Vitamins.—Vitamin A: It has been shown that the plasma of acutely jaundiced patients contains little vitamin A even though the liver may have large quantities of it. In chronically jaundiced patients, however, stores of vitamin A in the liver are much smaller than in patients with acute hepatitis or with extrahepatic biliary tract involvement.[8]

The low plasma vitamin A level in acute cases of jaundice seems to be due to failure of the liver vitamin A to reach the circulation. Thus in patients with hepatitis there is less rise of the vitamin A level in the plasma after a given dose of vitamin A than in nonjaundiced persons.[9] Large amounts of vitamin A given orally may increase the plasma vitamin A level by first saturating the liver parenchyma and then causing an overflow of vitamin A into the plasma. These observations suggest that patients with jaundice require large supplements of vitamin A. Doses of 50,000 to 100,000 units of vitamin A in oil are most likely to cause a rise of the plasma vitamin A level. The recent preparation of vitamin A in aqueous solution is better absorbed and more economical because a dose about half the unit value of the oily solution will raise the vitamin A level of the plasma to a similar height.[10] The vitamin A supplement should not be given in the form of cod liver oil, because the fatty acids in the latter might be injurious to the liver.[11] In patients who cannot take anything orally, vitamin A can be given parenterally, preferably in the form of vitamin A palmitate in aqueous dispersion.[12]

Vitamin D and Vitamin E: At present there seems to be no apparent need for or gain from additional amounts of vitamin D. In the experimental animal vitamin E prevents liver necrosis, and doses of 100 to 300 mg. of tocopherol daily have been suggested for hepatic injury in man.[13]

Vitamin K: Lack of vitamin K is manifested by characteristic symptoms. The need for this vitamin and the amount to be used in various types of jaundice is usually determined by the plasma prothrombin level. A good and prompt rise of the prothrombin level after the intake of vitamin K is frequently considered a sign of good liver function.

Water-Soluble Vitamins.—Vitamin C (Ascorbic Acid): Vitamin C, which is stored in only small amounts in the body, is depleted rapidly; therefore patients with jaundice should be given large doses of this vitamin (500 to 1,000 mg. a day) because it influences favorably carbohydrate and protein metabolism and prevents fat deposition.

Vitamin B Complex: The vitamins of the B complex group are possibly even more important for the jaundiced patient than the vitamins previously mentioned. This holds true particularly for the so-called *unknown* factors; therefore it is advisable to give jaundiced patients large supplements of natural vitamin B complex rather than only individual B complex fractions which are at present prepared synthetically. Although the need for thiamine hydrochloride, riboflavin, nicotinic acid and pyridoxine is indisputable, certain other biological substances, some of which are at present still unnamed, seem to have much greater influence than the aforementioned fractions. Moreover, it is not advisable to give large doses of the components of the B complex since unbalanced doses may produce liver injury. In the treatment of the jaundiced patient it is preferable to use crude liver extract, liver powder or yeast powder (or tablets) rather than the synthetic preparations. The recent experiences with folic acid and particularly with vitamin B_{12} [14] in liver disease are examples of the importance of the natural B complex preparations, because they show that some of the benefits which were obtained previously with liver extract, liver powder or yeast powder were probably, to some degree, due to the above two substances which are part of the B complex group. Vitamin B_{12} should be given in large doses (30 micrograms daily or more) to patients with liver disease.

MISCELLANEOUS DIETARY FACTORS

In planning a diet for a jaundiced patient one must consider not only the three main foodstuffs, carbohydrates, proteins and fats, but the various accessories. The average patient with liver disease should get a diet which is low in salt, particularly sodium. It is necessary to cut down the salt intake because in jaundice, particularly that due to liver disease, there is definite sodium retention,[15] which may in later stages lead to water retention, edema and finally ascites.

The quantity and quality of the diet are not the only factors to be considered in planning the dietary regimen of the jaundiced patient. One should realize that many of these patients have anorexia, nausea and/or vomiting. Hence the number of feedings, size of each feeding and its particular composition are important. It is at times preferable to serve small meals at frequent intervals in order to permit the patient to eat small amounts slowly rather than to offer him a large meal which will make him feel bloated, nauseated and anorexic for the remainder of the day. The patient who experiences such discomfort after eating one meal is not going to enjoy the thought of eating another meal. The daily food requirements should therefore be offered at frequent intervals in small portions and at appropriate times. When proteins are given as supplemental protein drinks, whether as hydrolysates[16] or casein mixtures,[17] they should be given after meals rather than shortly before a meal. The food should be prepared and served in as pleasant a way as possible, because many patients eat not only with their mouths but also with their "eyes and nose."

Parenteral Solutions.—If a patient is not able to take all his caloric requirements by mouth some arrangements for parenteral supplements must be made, the latter consisting of dextrose and/or amino acid solutions. Dextrose, however, is at times given intravenously for other reasons, circulatory and metabolic.[18] If parenteral fluids are needed they should be given judiciously and at the correct time. To give parenteral fluids to a patient before the larger meals will result in a decreased appetite and a lack of enthusiasm for that particular meal. If protein hydrolysates are given parenterally because the patient cannot ingest sufficient proteins otherwise, these fluids definitely should be given after the last meal. The parenteral injection of protein hydrolysates gives the patient in some instances a sensation of satiety and, particularly when given too fast, may actually lead to nausea with or without vomiting.

The dietary therapy should be so arranged that it does not interfere with other necessary therapeutic or diagnostic procedures. Since most jaundiced patients —in this series—seem to eat best in the morning, it is advisable to plan a good breakfast for them with somewhat smaller meals during the remainder of the day. Furthermore, necessary injections of crude liver, vitamins and antibiotics which are part of the therapeutic regimen should be given in the morning before a meal or long enough after a meal so that the patient will not be upset too shortly before or after mealtime.

MEDICINAL SUPPLEMENTS

Calcium.—In some patients with jaundice, particularly in those with severe hepatitis associated with toxemia, calcium should be given in various doses (10 to 20 cc. of a 10 per cent calcium gluconate solution) and at various intervals during the day. Calcium appears to neutralize[19] some hepatotoxins (guanidine and related compounds) which accumulate in the blood stream of patients severely ill with liver disease.

Antibiotics.—Penicillin and streptomycin are frequently indicated for treatment of infections associated with jaundice, regardless of how mild the infections may appear to be. These antibiotics are helpful especially in treatment of the surgical types of jaundice. In cases of hepatitis (virus type) aureomycin has given some striking results particularly in cases of hepatic coma as observed by others[20] and by me in this series. I did not have sufficient experience with chloramphenicol (chloromycetin®) for any comment as to its efficacy in cases of hepatitis.

Sedatives.—For sedation, paraldehyde, chloral hydrate and slow acting barbiturates are safest for icteric patients. Use of opiates is contraindicated unless absolutely necessary. Meperidine (demerol®) hydrochloride may be used as a narcotic. Salicylates are well tolerated and can be given freely as analgesics.

Laxatives.—Many icteric patients suffer from constipation. In them a mild saline laxative is indicated.

Digestants.—For patients whose illness is more chronic and who complain of flatulence, belching and abdominal discomfort, the judicious use of dilute hydrochloric acid, bile salts and/or pancreatic substance has proved helpful.

Antipruritics.—Pruritus is encountered mostly in cases of surgical jaundice and is frequently one of the complaints with which it is most difficult to deal. Acetylsalicylic acid and ergotamine tartrate have been of little help. The antihistaminics have not proved too efficacious in treatment of my patients. Procaine hydrochloride in a 0.1 to 0.2 per cent solution (1 to 2 Gm. of procaine hydrochloride in 1,000 cc. of 5 per cent dextrose solution) has offered striking relief to some patients with pruritus.

Diuretics and Diuretic-like Substances.—In some patients treatment with mercurial diuretics alone may give results; in others ammonium chloride and mercurials are better. In some cases the addition of hypertonic dextrose solution or dehydrocholic acid (decholin®) (10 cc. of 10 per cent solution) increases the diuretic effect. Mercurials should be used cautiously.

Testosterone.—The injection of testosterone has been of aid in a small group of patients with cirrhosis. The basis for use of this substance is theoretical, but clinical evidence has accumulated to indicate that a trial of it is worth while.[21] It is possible that testosterone aids in getting rid of ascites by acting against the excess of estrogenic substances which the liver is unable to destroy and perhaps more so by its anabolic character.[22]

Crude Liver.—Injections of crude liver are beneficial because they frequently improve the appetite of the patient and at times appear to promote diuresis by supposedly counteracting the antidiuretic principle found in patients with hepatic jaundice.

Salt Substitutes.—The administration of one of the saltlike substances may be helpful because it will aid the patient in following a diet low in sodium.

Condiments and Spices.—Use of pepper, salt, mustard and other similar substances is best avoided.

Fluids.—The fluid intake should be moderately restricted to around 1,500 cc. More severe restriction may lead to complaints by the patient.

Lipotropic Substances.—In the past few years much has been written about the so-called lipotropic substances which supposedly help fat transport in the body.[23] At present a number of individual lipotropic substances (methionine,[24] choline and inositol) mixtures of lipotropic substances and liver,[25] powdered liver[26] and gastric mucosa are available for therapeutic use. Studies by various workers have shown that these substances have therapeutic value in carefully selected patients with cirrhosis of the liver on a nutritional basis or in patients with fatty livers.[27] The results of lipotropic therapy in patients with acute or chronic hepatitis on a virus basis have been disappointing.[28] In acute hepatitis characterized by severe toxic fatty changes, such as those following the injection of carbon tetrachloride or other hepatotoxic drugs, the administration of lipotropic substances may be of some value[29] In general it may be stated that lipotropic substances appear to be of therapeutic value mainly in those patients in whom excessive fatty deposits in the liver are prominent features.

Alcohol.—Use of alcoholic beverages is prohibited for patients with jaundice. They are detrimental to patients with chronic hepatitis (on a deficiency basis) and may be harmful even to those with the virus form.[30]

PROCEDURES FOR TREATMENT OF SPECIAL CONDITIONS IN THE JAUNDICED PATIENTS

Acute Hepatic Coma—In cases of severe hepatic insufficiency (fulminant hepatitis or actual hepatic coma) large amounts of dextrose must be given intravenously. Occasionally in these patients continuous infusion of 5 to 10 per cent dextrose solution is necessary. In some patients the additional use of sixth-molar sodium lactate solution is of value. The dextrose solution should be reinforced with large doses of ascorbic acid, thiamine hydrochloride 100 to 200 mg., riboflavin and niacin (nicotinic acid) or nicotinamide.[31] Vitamin B complex in the form of crude liver extract should be given daily and in large doses (3 to 5 cc.). Methionine given intravenously is occasionally helpful. Intravenous administration of liver in the form of a concentrate (intraheptol®) gave striking results in a few instances of hepatic insufficiency. Vitamin K should be given in doses large enough to keep the prothrombin level at normal range. If these patients have much fluid, edema, anasarca and ascites, a 25 to 50 per cent dextrose solution can be given intravenously at slow drip as part of the carbohydrate quota and the remainder as a 5 or 10 per cent solution. Although there may be sodium retention one must be careful to check for the possibility of hypochloremia which may occur if these patients are kept for a long time on a salt-free diet. In hepatic insufficiency the administration of oxygen in high concentration by tent, mask or tube occasionally has seemed to be of great value. In some of these patients transfusions of fresh whole blood are of value because they combat both anemia and prothrombin deficiency. Sometimes plasma may be used in addition to fresh whole blood; the plasma however should be freshly prepared rather than a multidonor mixture. If the latter, it should have been irradiated with ultraviolet rays to prevent the possibility of homologous serum jaundice in the future.[32]

Extrahepatic Obstruction—Most patients who are jaundiced as the result of an extrahepatic factor have to undergo surgical intervention for relief of the obstruction. Adequate liver therapy before operation will make these patients better surgical risks and will result in a better course during the operation and postoperatively. In these patients particular attention must be given to the prothrombin bleeding and coagulation time, to the fluid and electrolyte balance and to the type of anesthesia they will receive. The prevention of anoxia of the liver—by giving the patient oxygen and keeping the blood pressure at an adequate level—during the operation is important in these cases.

Once surgical intervention is deemed necessary it should be performed at the optimal time. In face of a dropping icterus and otherwise good condition of the patient, the operation may be postponed. However, in face of an extrahepatic obstruction with rising icterus, rising nonprotein nitrogen, falling hippuric acid synthesis and lowered cholesterol esters, surgical intervention should be prompt.

Jaundiced patients who are being prepared for surgical intervention should receive some type of antibiotic therapy. In most instances penicillin is sufficient; in some, however, depending on the associated infection, streptomycin, aureomycin or chloramphenicol may also be administered.

Fibrosis (Mesenchymal Reaction).—The presence of fibrosis in the liver in patients with chronic jaundice is usually manifested by additional signs, such as ascites, edema, distended veins in the abdominal wall, esophageal varices and splenomegaly. In these patients a stricter regimen of salt-free diet, diuretics and administration of vitamin B complex factors is necessary. Salt-free serum albumin is useful in some patients.[33] In addition, some patients may require abdominal paracentesis. Experiences with pituitary adrenocorticotropic hormone (ACTH) in such patients are still too limited to permit comment on the efficacy of the agent.

Infection.—In a jaundiced patient the presence of an infectious process, whether part of the underlying disease state or whether secondarily superimposed, adds to the hazards of the case. Infection should be combated by one or more of the antibiotics and by more intensive liver therapy in general[34]

Hemolysis.—Some jaundiced patients have associated hemolytic phenomena. In these the factors causing hemolysis should be identified and removed if possible. Blood transfusions should be given as often as necessary to prevent anemia with the associated anoxia of the liver.

Convalescent Period.—Patients who are convalescing from jaundice, particularly those who are recovering from hepatitis, should only gradually return to their previous diet and activities. Many of these patients have to restrict the intake of fatty foods and alcoholic beverages. They should be careful to avoid exposure to excessive strain, infection or other influences which may decrease their resistance and lead to possible recurrence of the hepatitis. Patients with cirrhosis must watch their diet and abstain from alcohol indefinitely.

CONCLUSION

All jaundiced patients, whether they have hepatitis or extrabiliary tract conditions, have a certain degree of liver damage and should therefore be treated with an intensive liver regimen. Various steps in the present management of jaundice have been presented, and the basis for some of them has been discussed. All jaundiced patients, particularly before the exact nature of the jaundice is known, deserve the most intensive liver therapy in order to prevent some of the dire complications which may result from improper management of such cases.

Mortality Percentage of Patients with Medical Jaundice During Initial Hospital Admission

Types	1939-1944	1945-1950*
All jaundice cases	38.2	25.1
Infectious hepatitis	6.5	5.1
Toxic hepatitis	25.0	16.8
Cirrhosis with jaundice	63.0	38.8
Cirrhosis without jaundice	31.0	17.8
All cirrhosis cases	48.0	32.0 15.6†

* Patients treated through the month of May, 1950.
† If treated with lipotropic substances in addition.

The results of such a regimen as that presented above can best be gleaned from the accompanying table, which shows the immediate mortality of patients with medical jaundice before and after institution of the newer therapy.

30 North Michigan Avenue.

ABSTRACT OF DISCUSSION

Dr. T. L. Althausen, San Francisco: Dr. Steigmann's summary of the modern management of jaundice is excellent. There are some areas of disagreement in our handling of patients, but these are few. I would like to point out the necessity of giving supplemental vitamin D. Dr. Steigmann recognizes the importance of calcium metabolism in jaundice, because he advised the administration of salts of calcium. Supplemental amounts of vitamin D are also necessary because calcium even in large amounts is not absorbed well when there are excessive amounts of fat in the intestinal tract, whereas supplemental amounts of vitamin D will provide for more nearly normal absorption of calcium. With a few exceptions administration of bile salts is contraindicated in most diseases of the liver because bile salts stimulate the liver to secrete bile, and it does not seem therapeutically correct to stimulate a sick organ to greater activity, whether that organ be a sick heart or a sick liver. For this reason I believe that as a rule bile salts should not be administered to patients with jaundice. The third point is related to low salt diets, which are in most cases beneficial to patients with diseases of the liver. However, there is a certain amount of danger in overdoing a good thing, particularly if the patient has ascites and is being tapped. I saw at least two patients who were in a semicomatose condition after a prolonged period on a low salt diet and after removal of ascitic fluid but who regained consciousness immediately after the administration of sodium chloride. Stimulated by this experience, I determined the amount of sodium actually lost during a paracentesis and found that it may amount to as much as 15 Gm. I want to commend Dr. Steigmann on his discussion of the importance of judiciously timing the intravenous feedings. Such feedings definitely impair the patients' appetite when given shortly before a meal. This fact has never been emphasized sufficiently in the literature.

Dr. Frederick Steigmann, Chicago: Only in chronic cases of jaundice do I suggest administration of bile salts. As Dr. Althausen mentioned, patients with acute jaundice are not given bile salts because it is not desirable to stimulate a sick organ. In some instances I, too, have noticed that if the low salt diet is followed by the patient without careful observation by the physician, the patient may become hypochloremic.

ELECTROENCEPHALOGRAPHICALLY CONTROLLED ANESTHESIA IN ABDOMINAL SURGERY

CHARLES W. MAYO, M.D.
REGINALD G. BICKFORD, M.B.
and
ALBERT FAULCONER Jr., M.D.
Rochester, Minn.

The primary objective of the surgeon is to lower mortality and morbidity rates. For this reason he is always interested in developments that give promise of attaining this end. In the flush of enthusiasm about some new product or device the tendency is to think in terms of panaceas rather than to maintain a calm point of view and evaluate its true place in one's armamentarium. It is too early to classify the subject of this presentation, electroencephalographically controlled anesthesia in abdominal surgery. There is no field in medicine that the surgeon has followed with more interest and no specialty on which he has been more dependent than anesthesiology. Due credit must go to those physicians in active practice, physiologists and others in related basic science fields and those connected with pharmaceutical organizations, whose collective contributions since use of the first crude anesthetic agent have brought anesthesia to the present high plane of perfection.

Surgical anesthesia may be defined as the induced loss of sensation of a part, or of the body as a whole, with sufficient mental and muscular relaxation of the patient to permit optimal surgical technic for the operative procedure necessary. Short of this state, the patient has not arrived at a state of surgical anesthesia. Anesthetic agents vary because of their particular physical and chemical properties. One of the properties they have in common, however, is their ability to diminish and finally to produce loss of irritability and conductivity of nerve tissue when applied in adequate concentration. In general anesthesia, with certain aspects of which this paper is concerned, the agent or agents employed reach the nervous system by way of the blood stream. During the process of increasing the concentration of the anesthetic agent in the tissue, progressive inhibition of the normal function in the individual components of the nervous system is manifested by certain

Read before the Section on Surgery, General and Abdominal, at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

From the Division of Surgery (Dr. Mayo), the Laboratory of Electroencephalography, Section of Physiology (Dr. Bickford) and the Section on Anesthesiology (Dr. Faulconer) of Mayo Clinic.

reflex changes and alterations in spontaneous motor activity. From these changes the trained observer is able to make a fair estimate of the depth of anesthesia. On a basis of this estimate and his past experience he finds it possible in most cases to induce and maintain optimal conditions for the surgical procedure contemplated. The diagnosis of depth of anesthesia in this manner has never been an exact science but is truly an art.

In the hope that electroencephalographic changes occurring during surgical anesthesia might provide a basis for a more objective and exact estimate of the depth of anesthesia a critical study of these changes was made.[1] The investigation was confined primarily to persons undergoing operations in which nitrous oxide-oxygen-ether anesthesia was used. As an outcome of this work it was seen that there were changes in the electroencephalographic pattern of sufficient clarity, magnitude and consistency to allow these changes to be related to depths of anesthesia progressing from loss of consciousness to complete respiratory paralysis. These changes in pattern arranged in order of increasing depth of anesthesia seemed to fall naturally into seven levels.[1] The levels are indicated in figure 1

A study of the characteristics of the patterns occurring with increasing depth of anesthesia revealed the important fact that the total output of electrical energy per unit of time represented by the height and the duration of the brain waves was maximum in every case at a time closely approximating the lightest level of surgical anesthesia. As anesthesia became deeper there was a consistent and progressive drop in the total output of energy represented by the brain waves until at a level coinciding with respiratory paralysis this output of energy was, for practical purposes, zero

The constancy of the relationship between the output of electrical energy measured at the scalp and the depth of anesthesia suggested to one of us (R. G. B) the possibility of utilizing the brain potentials to regulate automatically the administration of certain anesthetic agents. To accomplish this an electronic integrator was added to the electroencephalograph. This served the purpose of storing the energy output until it had reached a certain predetermined amount, whereupon the stored energy was instantly released and the storage process begun anew. Thus, with an exceedingly active brain-wave pattern this cycle would be repeated with a much greater frequency than with an inactive brain-wave pattern.

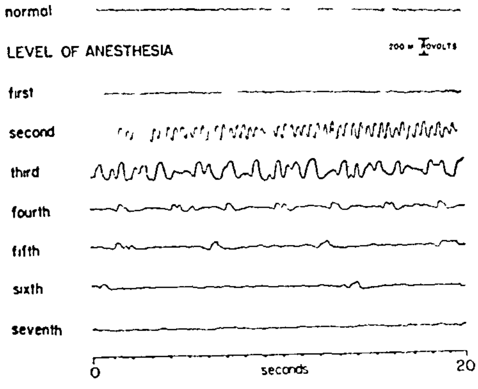

Fig 1 —Electroencephalographic levels of anesthesia (nitrous oxide oxygen ether)

Now it became possible to utilize the energy discharge at the termination of each of the cycles just described to "trigger" a relay circuit activating a pump A pumping system was designed so that each energy discharge would cause the propulsion of a fixed amount of anesthetic agent into a vein or an ether vaporizer In this manner a system was established which would administer the anesthetic agent (ether or thiopental [pentothal®] sodium) through the desired channels at a rapid rate when the brain-wave pattern revealed great activity and at a slower rate when the pattern revealed less activity

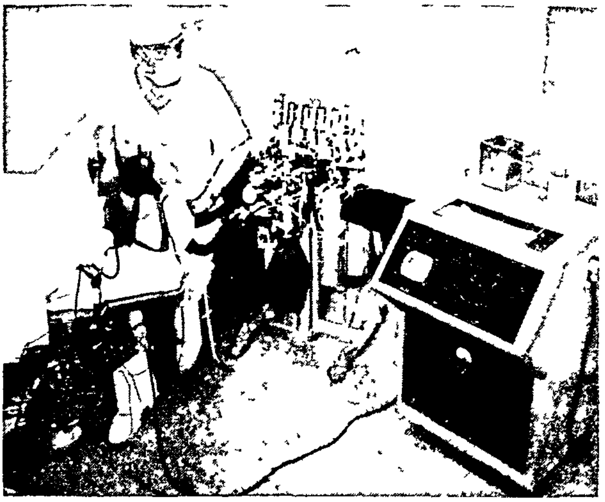

Fig 2 —Automatic administration of ether

Application of this device to the administration of thiopental sodium and ether to rabbits, cats and monkeys established the fact that a desired level of surgical anesthesia could be maintained automatically for long periods of time (two to three days) without human interference. The depth of anesthesia thus maintained could be established by suitable adjustment of the integrating mechanism. Experience demonstrated that this automatic system tends to compensate for factors which disturb equilibrium. For example, should there be a leak in the intravenous or inhalation channel or should the anesthetic agent be added by another means, the rate of administration governed by the system makes an appropriate compensation as soon as the disturbing factor is reflected in alteration of the brain-wave pattern

The idea of the automatic electroencephalographic control of anesthesia was developed by one of us (R. G. B.)[2] and co-workers, in collaboration with Drs Faulconer, Courtin and Soltero and Miss Haefliger Another of us (C. W. M.) became interested in it while it was still in the state of animal research, and he was privileged later to participate as a surgeon in the practical application of the system to man. To date it has been used in performing major surgical procedures on more than 50 adult patients of varying ages and of both sexes without untoward effect (fig. 2). The electroencephalogram foretells a change in depth of anesthesia many seconds before the change is apparent to an anesthetist. It instantly and automatically adjusts the administration of the agent to compensate for a change in depth. Thus it is more capable than the anesthetist of maintaining a constant level. If the surgeon will wait for the establishment of the necessary level of surgical anesthesia before opening the peritoneal cavity and, again after abdominal exploration, before starting the technical accomplishment of the main surgical procedure, the uninterrupted relaxation obtained by this automatic administration of anesthetic agents is most gratifying. However, the use of this method of anesthesia does not eliminate the need for the well trained anesthetist.

[2] Bickford, R. G: Automatic Electroencephalographic Control of General Anesthesia, Electroencephalog & Clin Neurophysiol 2: 93 96 (Feb) 1950

In addition to the practical potentialities of electroencephalographically controlled anesthesia related directly to clinical surgery, electroencephalography has opened a new door to research in the field of anesthesiology. Automatic anesthesia may even have a therapeutic value in certain neuropsychiatric conditions or physical states in which a constant degree of controlled rest and relaxation may be desirable. For the investigator who must depend on anesthetized animals for his studies this method offers for the first time precise control and objective evidence of the depth of anesthesia—an important consideration in the evaluation of the results of many investigations.

Continuing efforts in this particular field of experiment and study give promise of simplification and development of the apparatus to a state of compactness and reliability which will add much to the safety of administration of certain anesthetic agents and make the method more generally available to research projects. It seems to have great practical potentiality.

ABSTRACT OF DISCUSSION

Dr. Albert Faulconer Jr., Rochester, Minn.: It is not our purpose to propose the substitution of a rather complex machine for a competent anesthetist. We wish to make that very clear. We do feel that there are certain applications, immediate and potential, which can be made with this device, and they can be classified for convenience under four major headings: First, this device may find a field of usefulness in clinical anesthesia when applied in circumstances in which the prolonged maintenance of an even level of anesthesia is desirable. The fact that it is capable of accomplishing this end has been demonstrated in these studies. A potential field of usefulness, though as yet untested, might be found in the maintenance of an even level of anesthesia in patients to whom curare has been administered. There is now sufficient evidence that for practical purposes curare will have little or no influence on the functioning of the method under discussion. Second, if therapeutic value should be indicated in the prolonged maintenance of narcosis, it is reasonable to assume that this method might be adapted to that purpose. At present we are unaware of any recognized therapeutic procedures involving prolonged narcosis with the agents used to the present time. Third, perhaps the greatest immediate value to be derived from the use of this method lies in the field of its research application. There long has been a need for a definite objective control of anesthesia in many of the problems encountered in pharmacologic and physiologic investigations. Often the uncertainty introduced by the necessity of maintaining animals under anesthesia of uncalculated depths has an important bearing on the conclusions derived from the experiment. Up to the present time this variable has been controlled by the interpretation of certain isolated reflex phenomena which in themselves are notably inconstant. In addition to these research applications it is our belief that this method may constitute a valuable tool in the elucidation of the fundamental nature of anesthesia in the higher species of animal life. Fourth, in a more general way it is considered that the development of automatic control of anesthesia, which is an example of the application of the servomechanism theory, opens wide and interesting possibilities of automatic control in the entire field of medicine.

Dr. William L. Estes Jr., Bethlehem, Pa.: My only qualification to discuss this report is that I have seen this remarkable machine in action. It is most uncanny and dramatic to observe the automatic record of the patient's condition unfold, including both the electrocardiographic changes and the electroencephalographic record, while the little click every few seconds indicates likewise the automatic administration of small increments of the anesthetic agent. The mechanism by which all this is accomplished is most baffling to a mere surgeon. Although the full significance of a machine of this character in the field of anesthesia is at this time difficult to predict, the immediate potentialities are most impressive and seem epoch making. It is of extreme value and importance that study of the encephalographic patterns elaborated by this apparatus indicates that the changes in pattern follow the degree or depth of anesthesia and that from the stage of loss of consciousness with any increase in depth of anesthesia, the energy output of brain waves is gradually decreased. With the great advances in anesthesia in the last decade one has been impressed by the fact that the problems of anoxemia and of cardiac and respiratory arrest in the patient under anesthesia in no way seem to have been abolished. Some of the underlying etiological factors for lethal complications may lie either (1) in the increasing tendency to use and the apparent vogue for use of multiple anesthetic or analgesic agents in a single patient, or (2) in the idiosyncrasy of the patient to one or more of the drugs employed and abnormal reaction to minimal or conventional dosage. Present methods of measuring the effect of the anesthetic on the patient and of estimating the depth of anesthesia are relatively crude—simple recording of the pulse, respiratory rate and blood pressure or observing reflexes—and, as Dr. Mayo has pointed out, estimation of depth of anesthesia by these means is an art rather than a science. One step toward more accurate estimation of anesthetic effect has been the oximeter of McClure and his co-workers. And now this machine presented by Drs. Mayo, Bickford and Faulconer, while seemingly highly technical, provides an accurate and scientific record of the vital functions of a patient under anesthesia and a prompt indication of early deviation from the normal and thus will indicate the need for therapy to prevent impending serious complications or disaster far quicker and earlier than any previous means or modality. It would also seem that this method of recording a patient's physical functions opens up a new field of more scientific approach to gaging the effect of anesthetics and surgical procedures on patients and offers untold potentialities toward advancing our knowledge of the detailed effects of anesthetics as well as rendering their administration far more safe.

Dr. R. G. Bickford, Rochester, Minn.: This method of anesthesia control consists essentially of the application to the human of engineering principles that have been known since James Watt invented the governor for his steam engine. This type of control system, known technically as a servomechanism and exemplified by a household thermostat, was studied a great deal in the last war and the information gained was used in the construction of robot missiles and other automatic weapons. Many of the servomechanisms which exist in the human body have been described by Claude Bernard and later by Walter Cannon under the general term "internal hemostasis." What we have attempted in automatic anesthesia is to apply an external regulating system to the human body. This may be looked on as a form of "external hemostasis." The simple injection technic described has application outside the field of anesthesia for the control of the concentration of chemical substances in the blood. For instance, anticonvulsive drugs can be automatically administered until seizure activity disappears from the brain. If the sensing element is replaced by a Geiger counter, the system could be used to maintain a desired concentration of a radioactive substance, for example, radioactive iodine in the thyroid. We are hoping to explore some of these applications in the near future.

INTRAVENOUSLY ADMINISTERED SACCHARATED IRON OXIDE IN THE TREATMENT OF HYPOCHROMIC ANEMIA

Therapeutic Results, Potential Dangers and Indications

ELMER B. BROWN, M.D.
CARL V. MOORE, M.D.
CESAR REYNAFARJE, M.D.
and
DAVID E SMITH, M D.
St Louis

Saccharated iron oxide given intravenously has recently been used successfully by several groups of British investigators for the treatment of iron deficiency anemia.[1] The therapeutic response has been uniformly good; reactions have been both infrequent and mild. It is surprising that the preparation can be injected with relative safety since all other forms of iron administered parenterally have caused reactions so severe that their use had to be abandoned; these include ferrous citrate, iron citrate green, ferrous gluconate, ferrous ascorbate, colloidal ferric hydroxide and colloidal ferric oxide.[2] The toxic manifestations commonly observed with the last two compounds were nausea, vomiting, abdominal and lower back pain, lacrimation, nasal stuffiness, headache, flushing and swelling of the face, swelling and stiffness of the tongue, paresthesias, fever, rapid fall in systolic blood pressure, substernal pain and a sense of impending death. The earlier studies with these therapeutically unsatisfactory iron preparations, however, had demonstrated that injected iron is almost quantitatively converted into hemoglobin; and when the amount of injected iron is large (0.608 to 1.32 Gm.) the reticulocyte response is dramatic and the rate of hemoglobin regeneration maximal.[2b] For these reasons the discovery of a safe, effective form of parenteral iron therapy must be regarded as important. At the same time, it should be emphasized that there are few legitimate indications for the injection of iron since almost all iron-deficient patients respond well to oral therapy. Furthermore, if the dose is not carefully calculated, much larger amounts of saccharated iron oxide may be given than are needed to correct the deficiency, and excessive, potentially harmful deposits of iron in tissues may result.

The present report (1) describes the clinical and hematological responses of 10 patients with hypochromic microcytic anemia to the intravenous administration of saccharated iron oxide, (2) emphasizes the potential toxic effects of overdosage and (3) defines the indications for the use of saccharated iron oxide.

THERAPEUTIC RESPONSE TO INTRAVENOUSLY ADMINISTERED SACCHARATED IRON OXIDE

Saccharated iron oxide was given intravenously to 10 patients with hypochromic microcytic anemia. (See the accompanying table). The primary cause of iron deficiency in each instance was hemorrhage either from the uterus or from the gastrointestinal tract. Hypochlorhydria and poor diet were undoubtedly important contributory causes in several patients. Initial hematological values showed the following range of variations: red blood cells, 3.14 to 5.17 million cells per cubic millimeter; hemoglobin 5.8 to 9.8 Gm. per 100 cc., and mean corpuscular hemoglobin concentration, 25 to 31 per cent.

Three different preparations of saccharated iron oxide, each made by a different manufacturer, were used.[3] They contained 100 mg. of iron per 5 cc. According to Mannich and Rojahn,[4] saccharated iron oxide is a negatively charged colloidal solution of ferric hydroxide, stabilized by adsorption of alkali and sugar The methods by which these commercial preparations are made and their exact chemical compositions have not been announced. The three solutions were equally effective, however, and equally free of side reactions Some patients received 40 mg. of iron the first day, 60 mg. the second day and 100 mg. daily thereafter, in a few instances the initial dose was 100 mg. A few patients were given 200 mg. at a time, and occasionally the dose was repeated twice during a 24 hour period The total dosage varied from 700 to 2,000 mg. Injections were made through a 20 gage needle into an antecubital vein, care being taken to avoid any leakage outside the vein. After it became evident that the material did not cause thromboses, the time of administration was often shortened to 15 to 30 seconds.

Each patient showed an excellent clinical and hematological response. Within several days after the start of therapy, patients noted improved appetites Shortly thereafter, weakness became less pronounced. A reticulocyte peak occurred in all cases within six to 11 days; it was greater than 15 per cent in all but three patients and in one case reached a level of 21.2 per cent. The average daily rise of hemoglobin varied from 0.106 to 0.262 Gm. per 100 cc.; the over-all average rise for 10 patients was 0.177 Gm. per 100 cc These data are summarized in the table. The response in one patient is shown graphically in figure 1.

Reactions were minimal. One patient (K. M.) complained of nausea, abdominal cramps and a chill after receiving her first dose of 100 mg. of iron as saccharated iron oxide. Subsequently, the dose was reduced to 40 mg. and gradually increased to the original 100 mg without further reaction. Another woman (T. P.) reported transient pain along the course of the injected vein, due presumably to venous spasm. In a third subject with exceedingly small veins (E. C.) several

milliliters of the solution were accidentally injected outside the vein; the area became indurated, hot, swollen and painful. Acute discomfort subsided after 96 hours, but the induration took several weeks to disappear. There were no thromboses in spite of the fact that several patients received all injections into the same vein. Patients frequently reported that they felt abnormally sleepy for 10 to 15 minutes after receiving an injection.

POTENTIAL TOXIC EFFECTS OF OVERDOSAGE

The clinical experience reported by several groups of investigators[5] and that described in the preceding section establish the fact that up to 200 mg. of iron as saccharated iron oxide may be injected intravenously at one time with a high degree of safety for the patient. In all these studies great care was taken to give only enough iron to correct the deficiency. However, iron is often prescribed for patients who do not have hypochromic (iron deficiency) anemia, and its administration is frequently continued for months or years. If the same practice were followed for saccharated iron oxide,

* The letters MCV, MCHb and MCHb C denote mean corpuscular volume, mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration, respectively.

† Values from which average daily hemoglobin rise was calculated

An interesting effect of these preparations was discovered accidentally. Blood counts were usually obtained daily on each patient immediately before the iron was given. One day, on E. S., blood was drawn into diluting pipets immediately after the iron injection; the counts showed a profound granulocytic leukopenia (1,000 white blood cells per cubic millimeter with only 10 per cent granulocytes). More detailed study then revealed that the leukopenia was extremely transient. It appeared within five minutes after the iron administration but persisted for less than 30 minutes. The same phenomenon has been observed repeatedly but to a variable degree in other subjects, and it has been noted after use of each of the three iron preparations. The transient leukopenia is of no clinical import; its mechanism is unknown.

W.: Observations on the Intravenous Administration of Saccharated Oxide of Iron in Human Beings, J. Lab. & Clin. Med. **36**: 422, 1950. (c) Footnote 1.

one could easily inject much greater amounts of the metal than are normally contained in the body. For instance, one injection of 5 cc. of saccharated iron oxide (100 mg. iron) each week for a year would provide over 5 Gm. of iron, an amount roughly equivalent to all the iron in the blood and tissues of an average normal adult man. More serious abuse with two or three such injections per week would provide 10 or 15 Gm. It is known that only small amounts of iron are excreted by the body except through hemorrhage. Consequently, the injected iron would be retained in large part and might eventually produce toxic effects. Since, to date, excessive amounts of iron have never been given to human subjects, one must evaluate the seriousness of the danger (*a*) by reviewing those situations in which iron has accumulated under pathological circumstances in the tissues of patients and (*b*) by animal experimentation.

Large accumulations of iron have been observed in the tissues of human subjects in the following circumstances: (*a*) in hemochromatosis; (*b*) after a large number of transfusions, and (*c*) in adult Bantu natives of South Africa who live almost exclusively on maize diets and have chronic nutritional deficiencies. For the sake of comparison later, the following features of hemochromatosis are emphasized here: it occurs predominantly in adult males; is of unknown causation but probably related to an inborn error of iron metabolism; is characterized by excessive deposits of hemosiderin and hemofuscin in the liver, pancreas and other tissues, and is frequently associated with hepatomegaly, cirrhosis, diabetes and bronzing of the skin.

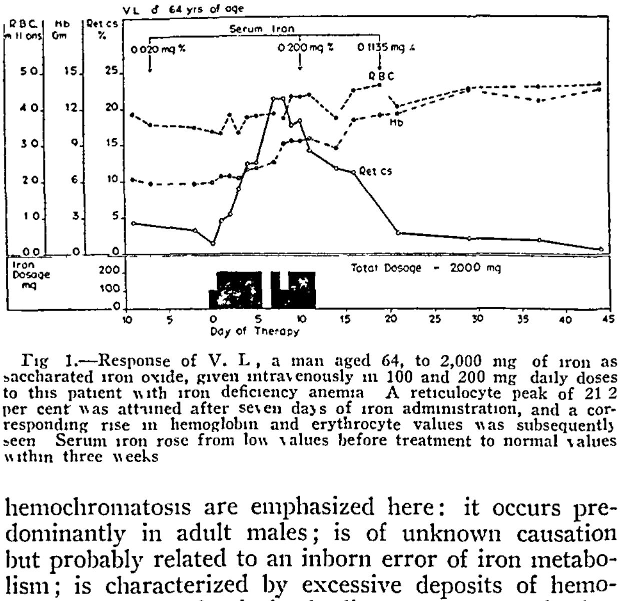

Fig 1.—Response of V. L, a man aged 64, to 2,000 mg of iron as saccharated iron oxide, given intravenously in 100 and 200 mg daily doses to this patient with iron deficiency anemia A reticulocyte peak of 21 2 per cent was attained after seven days of iron administration, and a corresponding rise in hemoglobin and erythrocyte values was subsequently seen Serum iron rose from low values before treatment to normal values within three weeks

Thirty cases of transfusion hemosiderosis have been described in the literature[6]; we have observed 10 additional patients, four of whom are still living. These 40 cases are essentially of three types: (*a*) pernicious anemia seen before the advent of liver therapy; (*b*) hypoplastic anemia, and (*c*) chronic forms of leukemia. In the reported patients the number of transfusions has varied between 12 and 290; one of our living subjects has received 534. If it is assumed that each transfusion averaged 500 cc. and that the amount of iron per 100 cc. of transfused blood averaged 50 mg., then the total amount of iron given to these subjects as hemoglobin varied from about 3 to 130 Gm. Hepatic enlargement was a frequent but not invariable result of these multiple transfusions, but fibrosis and cirrhosis were comparatively slight. Bronzing of the skin was usually noted in the subjects who received the larger quantities of blood. Diabetes was present in only six instances; in one case it appeared to be incidental, while in two others the only evidence for diabetes was an elevated fasting blood sugar level. There were mild to moderate amounts of hemosiderin in the spleen, pancreas, periportal lymph nodes, kidneys, adrenals and cardiac muscle with little evidence of fibrous tissue reaction. In six of the nine adults observed by us there were manifestations of cardiac failure.

Some clinical investigators have emphasized the similarity between transfusion hemosiderosis and hemochromatosis.[6b] There are differences, however, which seem important. Even though iron in the hepatic cells is definitely increased in transfusion hemosiderosis, the greatest deposits in liver and other tissues are in cells of the reticuloendothelial system. In hemochromatosis, by contrast, the iron deposition is largely parenchymal. Other differences include the infrequency of diabetes and the inconstant presence of true portal cirrhosis in transfusion hemosiderosis. More important than the relationship of these two disease states to each other, however, is the question whether the iron deposits actually cause the disturbances in hepatic, pancreatic and cardiac functions which do occur in hemosiderosis, no matter how inconstant. Since the deposition of iron from red cells which have been transfused into normal experimental animals does not produce fibrosis of the liver,[7] there appear to be other factors which cause the hepatic damage observed: the anemia itself, unrecognized serum hepatitis transmitted by one of the many transfusions or, in the case of hypoplastic anemia, hepatotoxic effects produced by the agents responsible for the marrow damage. About the only statements that may be made concerning the occasional association of diabetes with transfusion hemosiderosis are that the development of diabetes cannot be correlated with the number of transfusions and that it may be incidental. Chronic myocardial failure has never been observed in experimental animals given numerous transfusions. The patients with hemosiderosis in whom cardiac damage develops have usually had moderate to severe degrees of anemia for years and are often in the age group in which coronary artery disease is frequent. In spite of these considerations, and even though iron deposition in the myocardium is not great, one must assume until evidence to the contrary is produced that the iron is partly responsible for the disturbed cardiac function.

The third example of excessive deposition of iron in human subjects was described by the Gillmans[8] as cytosiderosis.[9] Cytosiderosis occurs in young adults of either sex among pellagrous Bantu natives whose food consists almost entirely of maize. The large amounts of inorganic iron in the diet apparently come from cooking utensils, and at least one of the factors which promotes excessive iron absorption is the low phosphorus content of the maize.[10] This disease is associated with hepatomegaly and varying degrees of portal cirrhosis; hemosiderin and hemofuscin may be found in large aggregates in the portal tracts. Intensely pigmented livers did not regularly show fibrosis, but in other instances cirrhosis was found superimposed on mild degrees of pigmentation.[8] There was no close correlation between the cirrhotic changes and the amount of iron present. For this reason, it is difficult to incriminate the iron as the cause of the fibrotic change. The Gillmans stated that many patients showed "a profound disturbance of carbohydrate metabolism" but cited no specific instance of diabetes and presented no histological studies of pancreatic tissue.

[9] The term cytosiderosis is used in this paper to refer specifically to the syndrome which the Gillmans[8] described and not as a synonym for hemochromatosis

From the above discussion it is clear that in hemochromatosis, transfusion hemosiderosis and cytosiderosis excessive amounts of iron are associated with pathological changes in several organs, but it is not certain in any instance that the iron is actually responsible for precipitating these abnormalities. It is necessary, therefore, to seek further information from the controlled experiments possible with animal studies. In extensive long-term investigations Polson [11] injected a colloidal iron preparation into rabbits and Cappell [12] injected saccharated iron oxide into mice and rats. In the latter experiments as much as 550 mg. of iron per kilogram of body weight was given. Both authors studied the tissue distribution of iron in detail. In addition they observed that: (*a*) there was no tendency for the development of hepatic fibrosis; (*b*) no iron was deposited in the pancreas except in histiocytes, and (*c*) pancreatic fibrosis did not occur.

It seemed desirable to repeat these observations using the same saccharated iron oxide solutions now being used for the treatment of human subjects. Accordingly, saccharated iron oxide at two dosage levels (0.5 and 1.0 Gm. of iron per kilogram of body weight) was given intravenously to four dogs. The amount injected daily varied from 100 to 300 mg. of iron: the time required for administration of the total quantity (4.54 to 9.44 Gm.) varied from 44 to 68 days. The levels of 0.5 and 1.0 Gm. per kilogram correspond roughly to 35 and 70 Gm. of iron for an adult human of average size and equal or exceed the amounts usually found in the tissues of patients with hemochromatosis. These animals have been fed a diet of purina® dog chow and have now been carefully followed for a period of 15 months. They are active and healthy in appearance. Weight has either remained constant or increased slightly. Hematological values have remained normal. The serum bilirubin levels and the sulfobromophthalein sodium clearance test of hepatic function have showed no change. Fasting blood sugar levels have consistently been within normal limits. Serum iron values were high during the period of injection but returned to the upper range of normal after all the iron had been given. Electrocardiographic tracings have been within normal limits. Data collected during the first eight months of observation on one of the dogs are summarized in figure 2.

Biopsy specimens, before and six months after the injections were begun, were obtained from the liver, spleen, pancreas, mesenteric lymph nodes, skeletal muscle and skin. The control sections showed no histological abnormalities. Those taken at six months revealed pronounced iron pigmentation of the liver, spleen and mesenteric lymph nodes, with less pigment in the pancreas, kidney and skin, but practically none in skeletal muscle. There was no increase in fibrous tissue in the liver, pancreas or other organs, and there were absolutely no cirrhotic changes. Sections of the liver stained for iron revealed the hemosiderin to be deposited in coarse granules aggregated into clumps with focal distribution in the sinusoids and portal triads. In addition to these larger deposits there was a diffuse, fine, granular deposition of iron in the hepatic parenchymal cells throughout the lobules and in individual Kupffer cells. Smaller deposits of iron were seen in the endothelium of the blood vessels, but none was found in the bile ducts. In the spleen, the iron was found in large quantities in the macrophages of the sinusoids and to a lesser extent in the capsule, trabeculae and beneath the endothelium of the blood vessels. There were small amounts of iron in the glomerular capillary tufts with faint diffuse deposits and rare fine granules in the renal tubules. The pancreas revealed only small amounts of iron confined to macrophages and to the subendothelial layers of the blood vessels. None was detectable in the acini or islet epithelial cells. Mesenteric lymph nodes showed large quantities of iron deposited in the macrophages in the central sinusoids with a less decided pigmentation of the peripherally located macrophages. Iron in the skin was confined to macrophages in the dermis, especially those around hair follicles; there was no pigmentation of the epidermis. The only iron seen in skeletal muscle sections was a trace in the endothelium of some capillaries. No pigment resembling hemofuscin was found in any of the sections.

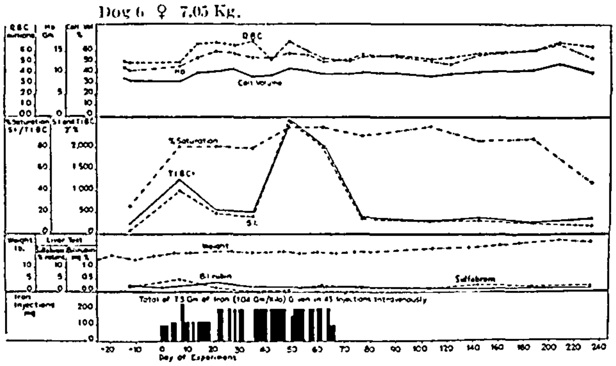

Fig. 2.—Response of dog weighing 7.05 Kg. to 7.3 Gm. (1.04 Gm. per kilogram of body weight) of iron as saccharated iron oxide given intravenously in divided doses during a period of 66 days. There were no significant changes in erythrocyte values, serum bilirubin or hepatic function as measured by sulfobromophthalein sodium clearance. The weight increased slightly during the 240 days of observation. The serum iron level rose to high values during the period of injections but fell to the higher limits of normal after the injections were completed though the percentage of saturation remained elevated. The letters S. I. and T. I. B. C. denote serum iron and total iron-binding capacity.

In the animal experiments just described there was no clinical, laboratory or histological evidence of any dysfunction produced by the injected iron. The periods of observation, however, were relatively short. It remains entirely possible that large tissue deposits of iron may cause anatomic or functional damage to organs not after 1 or 2 years but after 5 or 10. Until this possibility can be eliminated by further study, it is highly important that the injection of excessive amounts of iron into human subjects be diligently avoided.

INDICATIONS FOR THE USE OF INTRAVENOUS IRON THERAPY

Since the response of patients with hypochromic anemia to oral iron therapy is so uniformly good, there are few real indications for giving iron parenterally. It is true that many persons have mild gastrointestinal discomfort when oral therapy is begun; but if the initial doses are small and increased gradually over a period of three or four days to the usual therapeutic amounts, almost all patients can tolerate the iron. However, attention should be called to special situations in which parenterally given iron preparations will be helpful.

1. Hypochromic anemia in patients with ulcerative *colitis, with functioning colostomy, after extensive bowel* resection, and with sensitivity to iron. In these circumstances oral iron therapy may not be tolerated because gastrointestinal symptoms are severely aggravated or because sensitivity manifestations are produced. Two of our patients treated with saccharated iron oxide fell in this category. The first was K. M. (see table, case 1), a white woman aged 43, who in 1942 at an operation for acute intestinal obstruction underwent removal of a segment of gangrenous ileum infarcted by adhesions. Since the operation she has had intermittent bloody diarrhea, the cause for which has not been determined despite many examinations. As a result, hypochromic anemia developed. She has been given ferrous sulfate, ferrous gluconate, ferrous carbonate and other oral preparations on numerous occasions, but therapy has had to be discontinued each time because of severe nausea, abdominal cramps and diarrhea. The patient experienced a reaction when she received her first intravenous injection of saccharated iron oxide but tolerated subsequent injections well and had an excellent remission. The second patient was D. H. (case 4 on the table), a white woman aged 66 in whom hypochromic anemia appeared secondary to blood loss associated with a diaphragmatic hernia.[13] Oral ingestion of iron repeatedly caused itching of her skin and angioneurotic edema-like swelling of her face and hands. This woman sought relief from her anemia in a number of large medical centers. Each time her story of sensitivity to iron was greeted with skepticism, but each time the same manifestations appeared when any iron salt was taken by mouth. These symptoms were so intolerable that she refused to continue therapy. We gave her a test dose of radioactive iron (1 mg. per kilogram of body weight) in order to measure iron absorption; 25 per cent of the dose was absorbed, but the angioneurotic edema which appeared was unmistakable. Skin tests, patch tests and passive transfer tests done by Dr. Samuel Bukantz in an attempt to demonstrate the sensitivity were inconclusive. The initial dose of saccharated iron oxide given intravenously contained only 6 mg. of iron; the amount injected was then increased gradually to provide 24, 56, 100 and finally 200 mg. per day. There were no reactions whatever. Both clinical and hematological improvement was dramatic.

2. Hypochromic anemia in patients refractory to oral therapy. Several patients have been reported who failed to respond to oral intake of iron but who made excellent recoveries after receiving saccharated iron oxide intravenously.[14] Presumably, they were not able to absorb iron from the gastrointestinal tract. In no instance, however, has definite proof of poor absorption been obtained. Absorption studies were not actually made, and there was no evidence except the patient's word that the oral iron preparations had actually been taken. These cases must be extremely rare; the authors have never seen one. It is conceivable that iron absorption may be exceedingly poor in steatorrhea or sprue. Undoubtedly, however, oral iron therapy fails most frequently because its use is not restricted, as it should be, to the treatment of hypochromic anemias.

Other legitimate indications for parenteral iron administration may become evident later. In particular, it is probable that one could give saccharated iron oxide intravenously to hypochromic, pregnant women seen for the first time only a few days before the expected date of delivery and that enough of the iron would pass the placental barrier to protect the infant from developing iron deficiency during the first year of life. We have treated two such patients, but the babies of these mothers are still in the newborn period. There has not been sufficient time to determine whether they will or will not become hypochromic.

It is evident that in only two of the 10 patients listed in the accompanying table was there good reason to give saccharated iron oxide intravenously. The other eight patients would almost certainly have responded well to oral therapy. The parenteral iron was given only because its safety and effectiveness were being evaluated. As long as the total dose is carefully regulated, however, there are no known scientific reasons why it should not be used in any hypochromic patient. Practically, it would probably be more expensive to the patient and often considerably less convenient.

COMMENT

Saccharated iron oxide, given intravenously, has produced satisfactory hematologic and clinical remissions in patients with uncomplicated hypochromic anemia,[15] hypochromic anemia associated with pregnancy[16] and hypochromic anemia appearing in subjects with rheumatoid arthritis.[1h] Most authors have recommended that the initial dose be 20 to 50 mg. of iron and that the daily dose thereafter be 100 or 200 mg. until the deficiency is corrected. The total dose to be given can be calculated by using either of the following simple formulas:

$$\frac{\text{Norm. Hb.} - \text{Init. Hb.}}{100} \times \text{Blood Volume in cc.} \times 0.0034 \times 1.5 = \mathrm{Fe}_d$$

where: (1) The normal hemoglobin is assumed to be 15 Gm. for men and 13.5 Gm. per 100 cc. for women.

(2) Blood volume is estimated to be 80 cc./Kg. body weight.

(3) The factor 0.0034 converts grams of hemoglobin into grams of iron.

(4) The factor 1.5 is arbitrarily employed to provide for extra iron to replace the depleted tissue stores.

(5) Fe_d is the calculated dose in grams of iron.

---

[13] *Dr. Charles A. Doan referred this patient to us.*

[14] Davidson and Girdwood.[1b] Slack and Wilkinson.[1c] Sinclair and Duthie.[1h] Horrigan, Mueller and Vilter.[5b]

[15] Nissim.[1a] Davidson and Girdwood.[1b] Slack and Wilkinson.[1c] French.[1e] Nissim and Robson.[1f] Horrigan, Mueller and Vilter.[5b]

[16] Govan and Scott.[1d] Holly.[7a]

If one assumes that the body volume is 5,000 cc., he may multiply $\frac{5,000}{100}$ by 0.0034 by 1.5 to obtain the factor 0.255. The formula for determining the total dose may then be simplified to become:

$$(\text{Normal hemoglobin} - \text{Initial hemoglobin}) \times 0.255 = Fe_d$$

Hemoglobin values are used in terms of grams per 100 cc., not percentage of normal.

Within three or four days after injections of the saccharated iron oxide are begun, patients usually experience a sense of well-being, and reticulocytes in the peripheral blood begin to increase. The reticulocyte peak is reached in six to 11 days and is usually higher than with oral therapy. Hemoglobin values begin to rise about the end of the first week; the rate of hemoglobin regeneration is maximal.[2b] In the ten patients reported in this study, it varied from 0.106 to 0.262 Gm. per 100 cc. per day.

Reactions to saccharated iron oxide have been minimal. In a few of the reported cases generalized toxic reactions of mild degree have occurred[17]; several of these were observed, however, with solutions made by the investigators themselves rather than with the more carefully standardized commercial preparations. Thromboses and venous spasm have been observed in a few instances.[18] The incidence of reactions apparently rises as the individual dose is increased above 200 mg. In our 10 treated patients there was only one generalized reaction. One patient complained of transient pain along the course of the injected vein. Leakage of the saccharated iron oxide outside the vein caused a painful induration in one instance, but the lesion slowly disappeared without complication. We have noted two effects not previously described: (1) a transient, severe granulocytic leukopenia during the first 15 to 20 minutes after injection and for 10 to 15 minutes after it has been completed. No attempt is made to minimize the importance of these reactions. Their mildness is impressive only because other forms of parenteral iron are so much more toxic. None of the reported or observed reactions to saccharated iron oxide has been severe, but they are all troublesome.

Saccharated iron oxide, as a relatively safe parenteral iron preparation, is undoubtedly of value, but it does not represent a great therapeutic advance. Few patients are unable to tolerate or fail to respond satisfactorily to oral iron administration. Such patients in the past have been treated satisfactorily by transfusion of whole blood. There is, furthermore, the danger that saccharated iron oxide might be given in much larger amounts than are required to correct a deficiency or be given to persons who are not iron deficient. The excess iron will then be stored in tissues because the body is unable to excrete it; conceivably over a period of years it may produce fibrosis and functional changes in the liver, pancreas and other tissues. It must be admitted that the evidence attributing such chronic, toxic effects to large amounts of tissue iron is incomplete. In hemochromatosis, transfusion hemosiderosis and cytosiderosis the excessive iron deposits may be in no way responsible for the associated tissue changes, but one cannot yet be sure. The use of saccharated iron oxide, therefore, should be restricted to the treatment of iron-deficient patients. The dose to be injected must be calculated. The calculated dose should not be exceeded.

SUMMARY AND CONCLUSIONS

Excellent therapeutic results were obtained in 10 patients with chronic hypochromic anemia from calculated doses of saccharated iron oxide given intravenously. Blood values were restored completely to normal; rates of hemoglobin regeneration were maximal. Two of the patients had previously been unable to tolerate oral iron in therapeutic amounts. Reactions to saccharated iron oxide were infrequent and mild. These results confirm completely the reports of several British investigators on the efficacy of this form of iron therapy.

From animal experiments and from a review of the pertinent literature, it is concluded that no definite decision about the chronic, toxic effects of excessive deposits of iron in tissues can yet be reached. It is certainly possible that excessive deposits may produce tissue damage over a period of years. Because of this danger, it is imperative that saccharated iron oxide be given only to iron-deficient patients in a dose calculated to correct the deficiency.

There are relatively few specific indications for the parenteral administration of iron. However, when hypochromic anemia develops in patients with ulcerative colitis, with a functioning colostomy after extensive resection of the bowel or with sensitivity to iron (rare), oral therapy may so aggravate intestinal symptoms or may produce sensivity manifestations so troublesome that the parenteral use of saccharated iron oxide is preferable to oral therapy. In other patients who would respond satisfactorily to ordinary iron preparations given orally, saccharated iron oxide may be injected with relative safety if the dose is carefully calculated. From a practical point of view, its use in these patients does not seem desirable because: reactions, even though mild and infrequent, will prove troublesome; daily injections for 10 to 14 days will often be inconvenient, and the cost to the patient is likely to be considerably greater than that for oral therapy.

NOTE.—Since this paper was submitted for publication, the authors' attention has been called to the experience of Scandanavian workers with another form of iron which has been used parenterally. The preparation is marketed under the proprietary name ferrigen® by the Astra Co. of Sweden. The iron is said to be linked to a soluble, high-molecular carbohydrate, the compound being built in a manner similar to ferritin. Clinical experience with this material has been summarized by N. S. E. Andersson: (Experimental and Clinical Investigations into the effect of Parenterally Administered Iron, *Acta Med. Scandinav.*, supp., 241, 1950).

Groups and Clinics.—The ethical principles actuating and governing a group or clinic are exactly the same as those applicable to the individual. As a group or clinic is composed of individual physicians, each of whom, whether employer, employee or partner, is subject to the principles of ethics herein elaborated, the uniting into a business or professional organization does not relieve them either individually or as a group from the obligation they assume when entering the profession.

From the PRINCIPLES OF MEDICAL ETHICS of the American Medical Association.

Clinical Notes, Suggestions and New Instruments

FATAL VIRUS HEPATITIS OCCURRING IN AN INFANT THREE MONTHS OF AGE

BERNARD L. LIPMAN, M.D.
Philadelphia

Virus hepatitis, occurring as either infectious hepatitis or homologous serum hepatitis, is extremely rare in infants under 6 months of age. The following case report is of particular interest because of several possibilities in the causation and transmission of the disease.

The illness occurred 60 days after the administration of commercial irradiated blood plasma, and the mother of this infant had infectious hepatitis about three years prior to the birth of the baby.

REPORT OF CASE

History of Present Illness.—A boy 3 months of age was admitted to the Jewish Hospital, Philadelphia, June 20, 1950 with the complaint of jaundice of 24 hours' duration. Prior to this, from June 3 to 11, 1950, the baby had fever (ranging from 101 to 103 F.). The fever did not respond to adequate therapy with penicillin or sulfonamides. On June 9 the liver was noted to be 3.5 cm. below the right subcostal border. From June 11 to 19, 1950, the baby was asymptomatic; however, on the latter date the baby became jaundiced. He was promptly admitted to the hospital, where the jaundice rapidly became more intense. Coma and convulsions ensued, and death occurred 18 hours after admission. Laboratory data are given in the accompanying table.

Laboratory Data

	Date	White Blood Cells, %	Polymorphonuclear Cells, %	Lymphocytes, %	Monocytes, %
Hematologic data......	3/22/50	14,800	82	18	..
	3/23/50	17,800	78	22	..
	3/24/50	23,400	87	13	..
	6/ 4/50	8,500	78	12	10
Blood culture...........	3/26/50	Negative after 10 days			
Serologic tests...........	3/22/50	Comb's test negative			
	3/26/50	Serologic test for syphilis negative			
Urinalysis...............	6/ 4/50	Trace of albumin			
	6/20/50	Urinary urobilinogen absent; urinary bile pigments 2+			
Blood chemical studies..	6/20/50	Thymol turbidity 7 units			
		Cephalin flocculation 4+			
		Serum bilirubin 15.1 mg./100 cc.			
		Total serum proteins 6.1 Gm./100 cc. (albumin 5.0 Gm., globulin 1.1 Gm.)			

Past History.—The baby was born March 22, 1950 of a full term normal delivery and weighed 6 pounds 8 ounces (2,948 Gm.). The only abnormality noted was a moderate right metatarsus varus. During the neonatal period the baby had troublesome forceful vomiting, which began as soon as oral feedings were attempted. Five per cent glucose water, a weak evaporated milk formula, skim milk and a soybean milk substitute formula were all vomited. A roentgenogram of the chest and abdomen as well as a gastrointestinal series using barium contrast mediums were all normal. An antispasmodic drug, atropine methyl nitrate, combined with the use of evaporated milk formula thickened with cereal offered partial relief. Because of the possibility that prepyloric edema was responsible for the continuation of symptoms, two intravenous infusions of commercial irradiated blood plasma, 50 cc. each, were administered on April 3 and 4, 1950. All equipment used in the infusion had been autoclaved according to standard hospital technic. There was prompt subsidence of all symptoms following the plasma infusions, and the baby was discharged from the hospital April 12, 1950 weighing 6 pounds 12 ounces (3,062 Gm.) on a maintenance dose of atropine methyl nitrate 0.1 mg. before each feeding and thick cereal feedings. The baby did well at home, weighing 10 pounds 12 ounces (4,876 Gm.) June 3, 1950, at which time the present illness began.

Family History.—There was a strong family history of allergy. The mother had hay fever, and the maternal aunt had severe multiple ingestant and inhalant allergies. The mother had had infectious hepatitis in 1947. She was Rh negative and the father Rh positive, but there was no evidence, laboratory or otherwise, of erythroblastosis. This was her first child.

Report of Necropsy.—At necropsy gross observation showed that the liver was enlarged, with the anterior margin 3 cm. below the xiphoid process of the sternum and 2.5 cm. below the costal margin in the right midclavicular line. The substance was mottled red and tan, congested and firm. In the gastrointestinal tract the stomach was distended with gas. The muscle layers, particularly of the cardiac end of the stomach, were hypertrophied. The duodenum was congested. The papilla of Vater was small but the lumen was patent. Peyer's patches were slightly swollen. The entire mucosa has a deeply roughened appearance. The ileum contained a small amount of blackish material resembling altered blood. The colon contained clay-colored feces. The gallbladder was rather small and contained a little bile and mucus, which was squeezed with difficulty through the papilla into the duodenum.

Microscopically the liver was almost unrecognizable. At least half of the liver cells had been destroyed. The remaining cells showed swollen vacuolated cytoplasm and degenerating nuclei. Fragments of liver cells were seen in the sinusoids. In the region of what had been portal spaces there were numbers of proliferating pseudo bile canaliculi, with occasional transition between these and liver cells. Sinuses were overdistended in many places. At some places there were small hemorrhages where the sinus walls had been destroyed. Inflammatory cells, mainly mononuclear, were scattered throughout the tissues, with an occasional polymorphonuclear leukocyte among them. Fibroblasts were fairly numerous, especially in the portal spaces where there was a beginning fibrosis.

COMMENT

It seems certain that the source of the infection was either irradiated blood plasma or a carrier state existent in the mother. Unfortunately no hospital records exists of the lot number of the plasma; however, it is likely that the finishing number was 5523 E. It is our understanding that several or more finishing numbers may be included in the same lot. Correspondence with the pharmaceutical concern revealed that the bulk of this material was furnished to hospitals in the vicinity of New York City during Autumn of 1949 and the winter of 1949-1950. No reports of homologous serum hepatitis have as yet been forthcoming concerning this supply of plasma.

Although the incubation period of 60 days seems to incriminate irradiated plasma as the source of infection, one cannot be positive without further proof. It is also possible that a carrier state existed in the mother; however, it is likely that in utero infection would have been disastrous to the fetus and that postnatal infection would have had a shorter incubation perior. To my knowledge the carrier state cannot be proved without the use of human volunteers.

It would seem wise to be circumspect regarding the use of plasma in infants and children and for general supportive therapy to utilize various protein hydrolysates instead of plasma. Whenever plasma, irradiated or otherwise, is administered the lot number should be scrupulously recorded for reference should the need arise.

SUMMARY

A case of fatal virus hepatitis occurring in an infant 3 months of age is reported. The etiologic basis is uncertain, but the evidence points to either irradiated blood plasma or a carrier state of the mother.

8261 Temple Road (19).

Autopsy and pathological reports were prepared by Dr. Helen Ingleby, Department of Pathology, Jewish Hospital.

CONTRIBUTION TO THE SURGICAL TREATMENT OF ASCITES

Modification of the Crosby-Cooney Technic

MORRIS L. PARKER, M.D.
and
I. ALFRED BRECKLER, M.D.
Chicago

The surgical treatment of ascites has been revived in recent years as a result of the technic popularized by Crosby and Cooney.[1] They employ a glass button to establish a communication between the intraperitoneal space and subcutaneous tissue. A small pyrex® spool with flanged ends is sutured to the rectus sheath so that it runs from the peritoneal cavity through rectus muscle to the subcutaneous fat. Ascitic fluid moves through the button and into a space between the rectus fascia and subcutaneous fat and is there absorbed. There is little doubt that for the purpose intended the technic is feasible and of great benefit to many patients burdened with severe ascites.

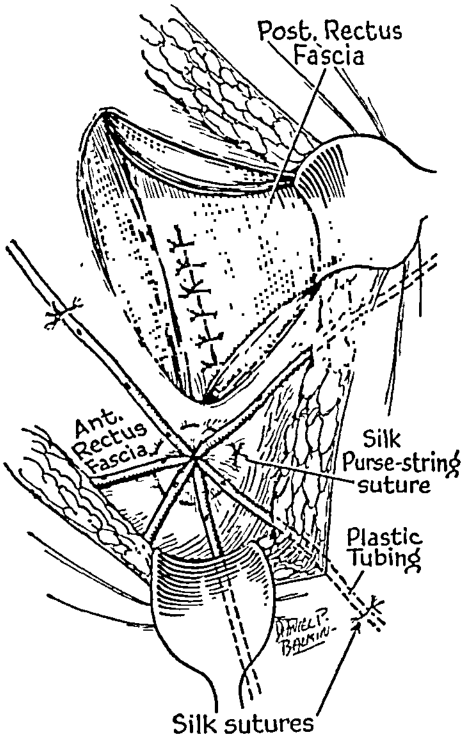

Fig. 1.—Posterior rectus fascia and peritoneum are closed. Note the purse string suture around the bundle, placed in anterior rectus fascia, and the silk sutures tacking the tubing in place

Schwei[2] has reported that 9 patients treated with the Crosby-Cooney button had remarkable control of their ascites. Warren[3] considered the method extremely beneficial. Unfortunately, as with every surgical procedure, there are instances of failure. Welch[4] studied 2 cases at autopsy and found that after two to four weeks the benefits obtained were negligible. He found that a subcutaneous cystic space with a dense fibrous wall had formed around the exit opening of the button and that effective absorption of fluid was almost completely impaired. Lord[5] has evidently heard of or seen similar failures, for he has tried stripping the rectus and external oblique fascia around the button to render the absorbing surface more reliable.

We have heard of similar difficulties with the glass button and have attempted to use another mechanical device to overcome the problem described. We employ a bundle of six polyethylene tubes (0.055 inches [1.4 mm.] inside diameter and 0.075 inches [2 mm.] outside diameter) approximately 6 inches (15 cm.) long. The tubing is bound together by two ties of surgical silk 1 inch (2.5 cm.) and 2 inches (5 cm.) from one end of the bundle.

Small holes are cut at intervals in the tubing. The bundle is then sterilized by boiling and inserted into the peritoneal cavity through rectus muscle and sheath as described by Crosby and Cooney.[1] The peritoneal end of the bundle has the shorter free ends, and the longer free tubes are then fanned out into the subcutaneous space, using as a guide a grooved director. (See figures 1 and 2 for exact technic.) We employ a plastic material which has been tissue tested in rabbits in our laboratories. It is nonirritating to tissue.[6]

It seemed to us that using tubing in this fashion would offer a much larger surface for absorption and that, being nonreactive, it would keep pocketing at a minimum. Our experience with this technic has been limited to 2 cases, but the results are sufficiently encouraging to warrant further trial.

REPORT OF CASES

CASE 1.—A white woman aged 57 had hepatic cirrhosis with increasing ascites, despite careful medical therapy, for a period of three years. Abdominal paracentesis was necessary with increasing frequency, until tapping was needed bimonthly prior to admission of the patient to the hospital. She suffered advanced malnutrition secondary to the severe cirrhosis and extreme generalized arteriosclerosis. There was severe ascites; the liver was palpable 5 fingerbreadths below the costal arch, and the spleen was definitely enlarged. Liver function studies showed pronounced hepatic damage.

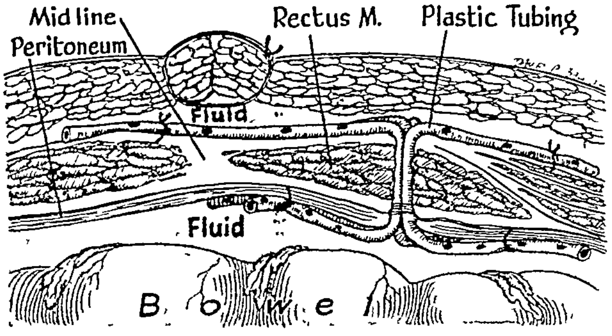

Fig. 2.—Cross section of the anterior abdominal wall showing the final position of the tubing within the abdominal cavity and under the subcutaneous layer.

After the insertion of the plastic tubing the patient remained hospitalized two weeks; successful convalescence was prevented by her general debilitation. Immediately after completion of the surgical procedure dependent edema developed over the sacral and pubic areas, and the anterior abdominal wall became decidedly edematous and remained so. Tapping was not necessary, although the abdomen seemed to increase slightly in size The advanced state of senility and emaciation contributed to making the patient completely uncooperative, and she finally refused any type of nourishment. As a result, she died in coma seven weeks after the surgical intervention. Even in such an advanced stage of debility paracentesis was not required, and fluid continued to be absorbed to the time of her death.

CASE 2.—A white man aged 51 had enjoyed good health until the three weeks prior to admission. He had been on vacation and had been pleased with an 18 pound (8.2 Kg.) gain in weight. Abdominal swelling, tenderness and nausea brought

him to his physician. He had been a moderate but continuous drinker of whisky for many years. Physical examination revealed a tense abdomen, obviously containing fluid, and an enlarged liver. Studies of hepatic function showed severe impairment of hepatic metabolism.

A set of plastic tubes was inserted, and at the same time liver biopsy confirmed the diagnosis of cirrhosis. There was definite improvement for the two weeks following surgical intervention while the patient was in the hospital. Five weeks after the operation so much subcutaneous fluid had collected that it was necessary to withdraw 2 gallons (7.56 liters) of ascitic fluid from the superficial pocket formed after the surgical treatment. There was no evidence at that time of intra-abdominal fluid. For the next three weeks the fluid did not reaccumulate. The patient expired in coma from hepatic failure, about two months after the tubes were inserted.

In neither case did fibrosis produce pocketing of fluid within the first four to six weeks, as Welch[4] had mentioned observing with use of the glass button. Both patients had adequate amounts of fluid freely absorbed from the subcutaneous spaces.

SUMMARY AND CONCLUSION

Two patients with severe ascites, both of whom died after hepatic failure, were treated with the insertion of plastic tubing that extended from the abdominal cavity to the subcutaneous tissue of the anterior abdominal wall. In both instances ascitic fluid was present in copious amounts in the subcutaneous tissues for a period of seven weeks.

Both patients were near death when treated, and in neither instance was an autopsy obtained. However, it seemed to us that the plastic tubing allowed extremely free passage of fluid into the subcutaneous tissue. Moreover, even when both patients were moribund, the outward movement of the fluid continued. Pocketing did not occur.

It is our hope that this modification of the Crosby-Cooney technic will be tried in other clinics.

30 North Michigan Avenue.

Council on Foods and Nutrition

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council:

JAMES R. WILSON, M.D., *Secretary.*

Borcherdt Malt Extract Company, Chicago.

BORCHERDT MALT SOUP EXTRACT POWDER, COCOA FLAVORED, consists of malted barley extract, potassium carbonate and cocoa.

Analysis (submitted by manufacturer).—Moisture 3.60%, total solids 96.40%, ash 3.20%, protein 9.30%, fat 0.9%, maltose 67.50%, dextrins 12.80%, starch 0.62%, crude fiber 0.22% theobromine 0.09% and caffeine 0.03%.

Calories.—3.7 per gram; 105 per ounce.

Use.—For use as a mildly laxative food adjuvant in the diets of children.

Libby, McNeill & Libby, Chicago.

LIBBY'S STRAINED AND HOMOGENIZED CHICKEN SOUP consists of chicken broth, chicken, carrots, wheat starch, celery, onions, salt, parsley and monosodium glutamate.

Analysis (submitted by manufacturer).—Total solids 9.50%, moisture 90.5%, ash 0.36%, fat 1.34%, protein (N × 6.25) 0.83%, crude fiber 0.15%, carbohydrates other than crude fiber (by difference) 6.92%.

Vitamins and Minerals	Per 100 Gm.
Total vitamin A activity	760 I.U.
Thiamine	0.0049 mg.
Riboflavin	0.026 mg.
Nicotinic acid	0.35 mg.
Calcium	12.0 mg.
Phosphorus	12.0 mg.
Iron	2.5 mg.

Calories.—0.43 per gram; 12.2 per ounce.

Use.—For use in the feeding of infants, convalescents, and others requiring a soft diet.

Reid Murdoch & Company, Division of Consolidated Grocers Corporation, Chicago.

MONARCH BRAND DIETETIC PACK APRICOTS—UNPEELED HALVES consists of the fruit itself packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 9.0%, fat (ether extract) 0.2%, protein (N × 6.25) 0.3%, ash (minerals) 0.5%, sodium 21 mg. per 100 Gm., potassium 156 mg. per 100 Gm.

Calories.—0.40 per gram; 11.3 per ounce.

Use.—For use in calory-restricted and other therapeutic diets.

MONARCH BRAND DIETETIC PACK ROYAL ANNE CHERRIES consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 10.0%, fat (ether extract) 0.5%, protein (N × 6.25) 0.7%, ash (minerals) 0.3%, sodium 16 mg. per 100 Gm., potassium 101 mg. per 100 Gm.

Calories.—0.48 per gram; 13.6 per ounce.

Use.—For use in calory-restricted and other therapeutic diets.

MONARCH BRAND DIETETIC PACK FRUIT COCKTAIL consists of peaches, pears, grapes, pineapple and Maraschino type cherries, packed in water without any added sugar or salt.

Analysis (submitted by distributor).—Available carbohydrates (total carbohydrate minus crude fiber) 10.0%, fat (ether extract) 0.2%, protein (N × 6.25) 0.4%, ash (minerals) 0.2%, sodium 18 mg. per 100 Gm., potassium 90 mg. per 100 Gm.

Calories.—0.45 per gram; 12.8 per ounce.

Use.—For use in calory-restricted and other therapeutic diets.

MONARCH BRAND DIETETIC PACK PEACHES—YELLOW CLINGSTONE (SLICED OR HALVES) consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 6.0%, fat (ether extract) 0.2%, protein (N × 6.25) 0.4%, ash (minerals) 0.2%, sodium 23 mg. per 100 Gm., potassium 97 mg. per 100 Gm.

Calories.—0.28 per gram; 7.9 per ounce.

Use.—For use in calory-restricted and other therapeutic diets.

MONARCH BRAND DIETETIC PACK PEACHES—ELBERTA FREESTONE (SLICED OR HALVES) consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 6.0%, fat (ether extract) 0.2%, protein (N × 6.25) 0.4%, ash (minerals) 0.2%, sodium 21 mg. per 100 Gm., potassium 136 mg. per 100 Gm.

Calories.—0.28 per gram; 7.9 per ounce.

Use.—For use in calory-restricted and other therapeutic diets.

MONARCH BRAND DIETETIC PACK BARTLETT PEARS consists of the fruit itself, packed in water without any added sugar or salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 9.0%, fat (ether extract) 0.3%, protein (N × 6.25) 0.2%, ash (minerals) 0.2%, sodium 16 mg. per 100 Gm., potassium 51 mg. per 100 Gm.

Calories.—0.40 per gram; 11.3 per ounce.

Use.—For use in calory-restricted and other therapeutic diets.

MONARCH BRAND DIETETIC PACK CUT WAX BEANS consists of the vegetable itself, packed in water without any added salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 4.0%, fat (ether extract) 0.2%, protein (N × 6.25) 1.4%, ash (minerals) 0.7%, sodium 34 mg. per 100 Gm., potassium 97 mg. per 100 Gm.

Calories.—0.24 per gram; 6.8 per ounce.

Use.—For use in low sodium and other therapeutic diets.

MONARCH BRAND DIETETIC PACK SLICED CARROTS consists of Chantenay carrots, packed in water without any added salt.

Analysis (submitted by manufacturer).—Available carbohydrates (total carbohydrate minus crude fiber) 6.0%, fat (ether extract) 0.3%, protein (N × 6.25) 1.0%, ash (minerals) 0.6%, sodium 53 mg. per 100 Gm., potassium 78 mg. per 100 Gm.

Calories.—0.32 per gram; 9.1 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Richmond-Chase Company, San Jose, Calif.

DIET-DELIGHT BRAND ASPARAGUS consists of the vegetable itself, packed in water without any added salt.

Analysis (submitted by manufacturer).—Total solids 5.20%, moisture 94.8%, ash 0.4%, fat 0.1%, protein 1.5%, available carbohydrates (total sugar as invert) 1.5%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 2.8% and sodium 70 parts per million.

Calories.—0.13 per gram; 3.7 per ounce.

Use.—For use in calory-restricted diets.

DIET-DELIGHT BRAND SPINACH consists of the vegetable itself, packed in water without any added salt.

Analysis (submitted by manufacturer).—Total solids 6.70%, moisture 93.3%, ash 1.2%, fat 0.5%, protein 2.1%, crude fiber 0.6%, available carbohydrates (total sugar as invert) 0.7%, carbohydrates other than crude fiber (by difference) 2.3% and sodium 215 parts per million.

Calories.—0.16 per gram; 4.5 per ounce.

Use.—For use in calory-restricted diets.

Council on Physical Medicine and Rehabilitation

REPORT OF THE COUNCIL

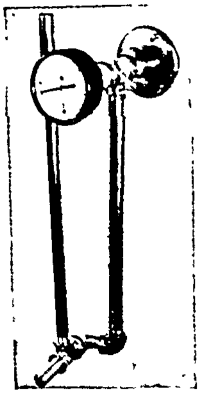
The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

Howard A. Carter, *Secretary.*

HOME WHIRLPOOL AERATOR ACCEPTED

Manufacturer: Home Physical Therapy Equipment Co., 141 East 56th Street, New York 22.

The Home Whirlpool Aerator is a device consisting of pipe, fittings, a venturi and a dial thermometer, designed to replace the ornamental spout on a bathtub or basin in the home and intended to agitate and aerate the water so as to give the patient the benefit of a whirlpool bath at any desired temperature up to that of the hot water supply. There are no electrical connections, home water pressure supplying the power for agitation and aeration on the same principle as that of the common laboratory water-driven aspirating pump. The air is drawn in through a perpendicular air pipe open at the upper end. The weight of the entire device is 2.3 Kg. (5 lb.), and it is 51 cm. (20¼ in.) in length. The shipping weight is 4 Kg. (9 lb.). Evidence was obtained from sources acceptable to the Council indicating that this device was well made and worked as claimed by the manufacturer. The Council on Physical Medicine and Rehabilitation voted to include the Home Whirlpool Aerator in its list of accepted devices.



Home Whirlpool Aerator

TRIPPE DIAPHRAGM INTRODUCER ACCEPTED

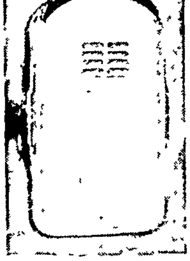
Manufacturer: Trippe Products Company, Hartsdale, N. Y.

The Trippe Diaphragm Introducer is a device intended to facilitate the insertion of vaginal diaphragms for contraceptive purposes. It is 21 cm. (8½ in.) in length, has a swivel tip at one end to facilitate releasing of the diaphragm and a hook at the other end to facilitate removal of the diaphragm, and makes a package weighing 40 Gm. (1⅓ oz.). The Council on Physical Medicine and Rehabilitation voted to include the Trippe Diaphragm Introducer in its list of accepted devices.

NATIONAL HEARING AID, VANITY MODEL 506, ACCEPTED

Manufacturer: National Hearing Aid Laboratories, 815 South Hill Street, Los Angeles 14.

The National Hearing Aid, Vanity Model 506, is an electric device recommended for the rehabilitation of the hard-of-hearing. With the exclusion of the clothing clips at the side, the case measures 129 by 60 by 24 mm. (tapering to 20 mm.). The weight of the case alone is 111.5 Gm. With the batteries, receiver cord and receiver, it weighs 195.5 Gm. The Council's test showed that electro-acoustic measurements, material, construction and performance were as reported by the manufacturer. The Council on Physical Medicine and Rehabilitation voted to include the National Hearing Aid, Vanity Model 506, in its list of accepted devices.

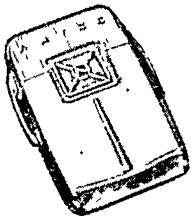


National Hearing Aid, Vanity Model 506

MAICO QUIET-EAR HEARING AIDS, MODELS G AND H, ACCEPTED

Manufacturer: The Maico Company, Inc., 21 North Third Street, Minneapolis 1.

The Maico Quiet-Ear Hearing Aids, Models G and H, are electric devices of conventional shape and arrangement; each measures 60 by 22 mm. in width and thickness. They differ, however, in length and weight. Model G measures 111 mm.; Model H, 99 mm. The transmitter unit of Model G weighs 119 Gm.; that of Model H, 122 Gm. Model G has a slightly higher battery drain and a correspondingly higher acoustic gain. The Council's investigation showed that the electro-acoustic properties, material construction and performance were as represented by the manufacturer. The Council on Physical Medicine and Rehabilitation voted to include the Maico Quiet-Ear Hearing Aids, Models G and H, in its list of accepted devices.



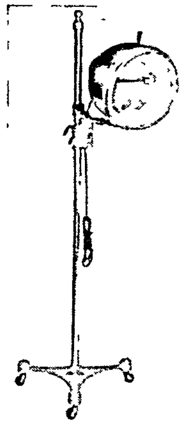
Maico Quiet-Ear Hearing Aid, Models G & H

GLOLITE LUMINOUS INFRARED RAY LAMPS, MODELS 439, 751, 1151 AND 1451, ACCEPTED

Manufacturer: Paul E. Johnson Manufacturers, Inc., 2508 South Parkway, Chicago 16.

The Glolite Luminous Infrared Ray Lamps emit both visible and infrared radiation in the range from 7,000 to 80,000 angstroms for therapeutic purposes. All four lamps are floorstand models and require a source of either direct or alternating current at 110 to 120 volts. Model 439 has a 450 watt heating element. Models 751, 1151 and 1451 require 660, 1,100 and 1,450 watts, respectively. The source of radiation for all lamps is made of resistance wire embedded in a nonmetallic substance. The dimensions and weights are as follows:

Model	439	751	1151	1451
Weight				
unpacked, Kg........	6.5	16.2	18	23.5
unpacked, lb.........	14.5	36	40	52
shipping, domestic, Kg.	8.5	19.5	21.5	27.5
shipping, domestic, lb.	19	43	47	61
shipping, foreign, Kg.	14.5	29	31	39.5
shipping, foreign, lb..	32	64	68	88
Height				
unpacked, cm.........	143	170	182	187
unpacked, in.........	57.5	68	73	75



Glolite Luminous Infrared Ray Lamp

Evidence from sources acceptable to the Council indicated that these lamps are satisfactory generators of radiant heat for therapeutic purposes. The Council on Physical Medicine and Rehabilitation voted to include the Glolite Luminous Infrared Ray Lamps, Models 439, 751, 1151 and 1451, in its list of accepted devices.

MICROTONE "CLASSIC" HEARING AID, MODEL T9, ACCEPTED

Manufacturer: The Microtone Company, Ford Parkway on the Mississippi, St. Paul 1.

The Microtone "Classic" Hearing Aid, Model T9, is a conventional electric hearing aid. For operation it requires a 1.5 volt A-battery and a 15 volt B-battery, both of the zinc-carbon type. With batteries it weighs 164.7 Gm. The external dimensions, excluding the clips, are 78 by 56 by 20 mm. Tubes, microphone, volume control and sealed amplifier unit are all removable. Evidence from acceptable sources as to electro-acoustic properties and clinical performance showed that this instrument was satisfactory. The Council on Physical Medicine and Rehabilitation voted to include the Microtone "Classic" Hearing Aid, Model T9, in its list of accepted devices.

LET'S KEEP AMERICA HEALTHY

A Guest Editorial

JOHN EDGAR HOOVER
Director, Federal Bureau of Investigation, United States Department of Justice

The life of a nation, in many respects, is similar to the life of an individual. A nation is born, grows in strength, is beset by ills and, unless properly cared for, may succumb to a fatal disease. Like an individual, a nation, in order to survive, must be healthy: physically, intellectually and spiritually. However, though human life, physically speaking, must have an end, a nation, kept strong, virile and healthy by the combined efforts of its citizens, can have life forever.

America, in this mid-twentieth century year, is a strong nation, great in material possessions and rich in spiritual resources. Born amid turmoil, a mere infant among the great powers of Europe, it possessed sturdy tissues, strong muscles and a sound heart. The founding fathers, in laying the foundations of America, planned well. The concepts of democracy, free government and the dignity of the individual were the beacon lights, the compasses of direction, guiding the paths of Americans toward the magnificent achievements of the next century and a half. Freedom of speech, religion and the press, embedded in a government of law, was the matrix in which we developed. America grew quickly from an infant into a bounding youngster and today into the mature responsibilities of adulthood.

But today the germs of an alien ideology, Communism, are attempting to infect the blood stream of American life—and to destroy the America we love and cherish. These Communist germs, spawned in the swamps of iniquity and terror, have blotted out, for one third of the world's population, the sunshine of free thought, independent research and unfettered inquiry. They have "sickened" many nations and literally killed countless persons. These germs are infectious and deadly, easily transmitted and often difficult to detect. This is America's task today, if we are to survive as a nation: to kill these Communist germs and to increase the strength and vigor of American resistance. In other words we must make democracy ever more workable, mature and worth while.

The physicians of America, by the very nature of their training, can render inestimable services in this ideological fight. Medical science is interested in cause and effect, in careful diagnosis, detection of specific symptoms and the prescribing of cures which will eliminate the cause of the malady. Physicians realize the value — in fact, the essential need — of clinical inquiry, unhampered by preconceived prejudices and suppositions; the calm appraisal of facts, and the absolute requirement that injuries and sicknesses be treated by professional, competent hands, not by amateurs and the inexperienced. Hysteria, impulsive actions and decisions not based on all the facts may mean disaster.

The fight against Communism must be waged, if we are to win, on the same principles which have enabled the medical profession to render such magnificent services for the American people. Communism is not something mystifying, impenetrable or impervious to observation. Not at all. Communism, despite its philosophical trappings and double talk veneer, can be analyzed. Through the stethoscope of observation and study, we can learn "what makes it tick." Communism means deceit, hypocrisy and duplicity, the glorification of force and violence, the destruction of liberty and freedom, the triumph of the state over the individual, the enthronement of falsehood, injustice, inequality and terror as the accepted standards of conduct. These are the central themes of Marxism-Leninism; the heartbeats of an atheistic philosophy which denies the spiritual basis of man's existence on earth. If these principles conquer the world, Western civilization—the way of life which has made possible the achievements of America — will be obliterated. The Communists, within minutes, would expunge 2,500 years of human history.

Americans, having learned the true inner meaning of Marxism-Leninism, will be alert to the hypocrisy of Communist siren calls. They will realize that when a Communist speaks of "peace," he really means "war," that when he poses as a champion of "free government" he, in fact, means the dictatorship of a ruthless minority. Communists are disloyal to our democracy; their allegiance is to Moscow. They would siphon away the free spirit of America, destroy the concepts of 1776 and establish a Soviet America—to become an "outpost" for Russian imperialism.

The FBI is the governmental agency designated to protect the internal security of the United States. The President in a directive dated July 24, 1950, called on all law enforcement agencies, patriotic organizations and individuals to report any information coming to their attention concerning espionage, sabotage and subversive activities to the FBI. The FBI, as the investigative arm of the United States Department of Justice, is a fact-finding agency. Our task is to obtain the facts, completely, accurately and impartially. The physicians of America, like other citizens, can best help in the protection of the nation's internal security by reporting immediately to the FBI any information of this nature which might come into their possession. The FBI is not interested in opinions or ideas, idle rumor or malicious gossip—only in facts. Like you, as physicians, we want to know the unvarnished facts of the case. To fulfil our responsibilities, we seek to determine all available facts and then forward them without comment or evaluation to the Department of Justice. The FBI is not a policy-making agency. It does not decide whether there will, or will not, be prosecution. That decision rests exclusively with the Attorney General and his assistants.

Americans can defeat the Communist challenge—and in a democratic manner. Witch hunts, hysteria and vigilante actions are repugnant to the democratic tradition. They weaken the majesty of law and provide the Communist agitators with additional talking points. If each person in America would stop and think, learn to "peel off" the "outer skin" of Communism, often deceptively painted with glittering promises and glorious utopias, and recognize Communism for what it is—terror and injustice—then America would have no fear.

The keys of victory must be alertness, eternal vigilance and the maintenance of calmness. A healthy nation, like a healthy body, must receive the unstinting cooperation of all its component parts; if one part fails to carry its share the whole organism is weakened. America, at this critical hour, must remain strong and healthy. This is the task of each and every person.

MEDICAL EDUCATION IN TIME OF NATIONAL EMERGENCY

The statement of the Joint Committee on Medical Education in Time of National Emergency which appears on page 1111 of this issue, presents the recommendations of the Association of American Medical Colleges and the Council on Medical Education and Hospitals with respect to the conduct of medical education in the present national emergency and its possible sequelae. This statement has been submitted to the Health Resources Advisory Committee to the National Security Resources Board and to the National Advisory Committee on the Selection of Doctors, Dentists and Allied Specialists to the Selective Service System. These committees have been assigned major responsibilities by the President and the Congress for planning and regulating the mobilization and utilization of medical manpower in the present emergency.

The aim of the Joint Committee's statement is to emphasize the importance to the health, safety and interest of both the armed forces and the civilian population of a continuing flow of well trained physicians and to point out that to provide such a flow the quality of medical education must be vigilantly guarded. The statement also points out that of parallel importance is the continued training of graduate students in the basic sciences to provide the personnel trained in these fields so urgently needed to staff the preclinical departments of the medical schools and for the continuation of basic research in the medical sciences.

The statement makes recommendations on the handling of a number of specific problems, including the maintenance of an adequate supply of preprofessional students, the obligation of medical students to serve their country after completion of training, the broadening of the medical curriculum to meet the special medical problems that accompany a national emergency, the need for an increase in the production of physicians, the faculty requirements of the medical schools and the importance of maintaining a strong program for the training of residents.

Because experience has shown that such a program produces immature and incompletely trained physicians, the Joint Committee specifically recommends against the adoption of an accelerated program of the type employed in World War II. Adherence to such a program over a prolonged period would have an unquestioned deleterious effect on the quality of the medical schools. Since these schools constitute in truth a vital national resource, their integrity must be preserved as a matter of national interest. Instead of the accelerated program, the Joint Committee recommends that the academic year be extended in all schools to provide the additional training that will be needed by physicians to meet the special problems occurring in time of national emergency. Thus, an extension of the academic year would make it possible to give more training in such subjects as the prevention and treatment of radiation injuries, bacteriologic warfare, chemical warfare, civilian disaster relief, public health, preventive medicine, and epidemiology in relation to disaster areas, traumatic medicine and surgery, industrial medicine and rehabilitation and utilization of manpower.

On the basis of the experience with the AST and V-12 programs in World War II, the Joint Committee also recommends against placing medical students in uniform or having them subsidized as a group by the government. Instead it recommends that consideration be given to a program of government scholarships to be awarded on the basis of economic need and demonstrated academic superiority to students recommended by the medical schools. The committee also recommends that there be consideration of a program of government loans for students needing such assistance.

The statement of the Joint Committee has been carefully and thoughtfully prepared after conferences extending over more than four months with medical educators, representatives of government agencies and representatives of the medical profession. Of much help were the extensive studies made after the end of

World War II by the Committee on Preparedness for War of the Association of American Medical Colleges. This statement presents the carefully weighed thoughts of outstanding medical educators and should receive the serious consideration that it deserves.

MIDCENTURY WHITE HOUSE CONFERENCE

Concern for the health and welfare of children is an old American habit. The repetition of this concern by the decennial White House Conferences has now become a custom. At approximately 10 year intervals since President Theodore Roosevelt called the first conference in 1909 to plan for the care of dependent children, the president in office has gathered together the leaders in health, welfare and education to take stock of current practices and lay plans for further improvement of the children of the nation.

Among the many recommendations of the first White House Conference was the creation of a Children's Bureau. This Children's Bureau, created in 1912, gave leadership to the second White House Conference in 1919 under President Woodrow Wilson, as the closing activity of the "Children's Year." This conference was concerned essentially with child welfare standards and the health of children and mothers. Though many of its recommended child welfare laws and child health practices were controversial, those with merit have survived.

President Herbert Hoover called the third White House Conference on Child Health and Protection in 1930 to study the "present status of the health and well-being of the children of the United States . . . to report what is being done, and to recommend what ought to be done and how to do it." This third conference widened the range so that all children were included, not only those who were dependent or handicapped.

The 1940 White House Conference on Children in a Democracy was called by President Franklin D. Roosevelt. It was much broader in scope than any of the others, considering for the first time economic resources, religion, housing, play and recreation, as well as health, social welfare and education. One of the outcomes was the impetus given to the programs for handicapped children.

The Midcentury White House Conference on Children and Youth, to be held in December 1950, "bases its concern for children on the primacy of spiritual values, democratic practice and the dignity and worth of every individual. Accordingly, the purpose of the conference shall be to consider how the mental, emotional, and spiritual qualities essential to individual happiness and responsible citizenship can be developed in children and what physical, economic, and social conditions are deemed necessary to this development."

It is apparent that the Midcentury White House Conference will attempt to organize all the information available on what influences healthy personality development and, on the basis of this information, point the way to better organized mental hygiene activities. Qualified persons concerned with the home, the church, the school, health service, social service, recreation, employment and a number of other activities will pool their information and discuss ways to plan proper guidance during childhood and adolescence.

Physicians are interested in the physical and emotional problems of children. They should, therefore, be vitally interested in the deliberations of the Midcentury White House Conference. Physician delegates will have an opportunity to influence the thinking of the people of the United States on how best to accomplish this important objective of healthy personality development.

The fact that the Midcentury White House Conference is held when there exists a sharp controversy over compulsory health insurance should not prevent physician delegates from participating in the conference and contributing to its development. White House Conferences have become an American tradition. They are held each 10 years irrespective of the party in power and have been generally constructive. Physicians should actively participate in the conference to promote constructive results and prevent political manipulation.

MATERNAL DEATHS—ONE IN A THOUSAND

The Journal takes pride in announcing that for the first time in history the maternal mortality rate for a large nation—the United States of America—has been pushed slightly below the apparently irreducible minimum of 1 maternal death per 1,000 live births. When the 1949 rates for Sweden, Norway, Denmark, the Netherlands and New Zealand become available, one or more of these small countries with homogeneous populations may join the United States in the select group of countries with maternal mortality rates of 1.0 or less. The 1933 rates for the United States, Sweden and (the whites of) New Zealand were 6.2, 3.1 and 4.4. Reductions in maternal mortality in the United States are, however, remarkable because they have been made in a population which contains, as a result of immigration, many diverse groups from the health standpoint. According to compilations of the number of maternal deaths and live births in the several states by the Bureau of Medical Economic Research of the American Medical Association, the provisional 1949 maternal mortality rate for the entire United States — counting all maternal deaths among all classes and groups in the entire country—was closer to 1.0 than to 0.9 on the basis of the fifth revision of the Manual of the International List of Causes of Death (1938). Some of the state and city health departments used the fifth and others used the sixth revision (1948) of the International List in coding the causes of deaths in 1949. Hence, the "true" national maternal mortality rate for 1949, a transition year in coding the causes of death, may never be known. The 1948 rate was 1.2.

Rarely has THE JOURNAL had the opportunity to call to the attention of the world in such definite terms the extraordinary accomplishments of the American medical profession, aided and abetted by auxiliary personnel and unequaled hospital facilities. But it is more than a story of tremendous medical progress. The fact that the chances of an expectant mother surviving the diseases of pregnancy, childbirth and the puerperium are now better than 999 out of 1,000 is truly a story of human and social progress.

This great record in maternal care takes the medical historian back to the days of Semmelweis in Austria, who led the medical profession toward the ideal of extreme cleanliness in maternity cases—the true pioneer of antisepsis in obstetrics. Previously, Oliver Wendell Holmes had pointed out the contagiousness of puerperal fever. One also thinks of Lister, a pioneer in antisepsis. It also takes one back to the late 1920's and early 1930's—when many of the soldiers, sailors and marines now fighting in Korea were born—when the maternal death rate was seven times as high as in 1949.

This glorious achievement of medical progress has not been limited to the wealthier states with almost exclusively white populations. In 1949 there were 30 states with rates less than 1.0, two at exactly that level and only 17 above. The highest state rate of 2.3 in 1949 for Mississippi was only one half of the lowest state rate, 4.3, in 1933. An examination of the rates for the different states indicates areas in which further improvement can be expected, but it is clear that maternal mortality is no longer a nationwide problem. Of course, it will be more difficult to maintain an extremely low level as the rate approaches even closer to 0.

What accounts for this phenomenal reduction in maternal mortality from 6.2 in 1933—the first year in which all of the states were in both the death and birth registration areas—to less than 1.0 in 1949? The increasing percentage of births in hospitals is an important factor, although improvements in the medical care provided in home births have been pronounced. A second factor is the development of a concept of prenatal care which stresses early diagnosis of some of the conditions which formerly contributed to death. Health education, particularly that given by the public health nurse in prenatal care, has aided greatly. In many cities the maternal health program of the local health department has been effective in reducing maternal mortality. In the actual treatment of complications, the basic factors in the last decade and a half have been the administration of sulfonamides, antibiotics and whole blood or blood derivatives. But steady improvement in undergraduate and postgraduate medical training in obstetrics is the most important factor in welding together these other forces. Unlike the trend in many nations, the number of births attended by midwives in the United States is being rapidly reduced. For a number of years many state and county medical societies have had special committees which review every maternal death in their areas and use their findings as a basis for improving all aspects of prenatal, intranatal and postnatal care. These study groups of organized medicine have been a tremendous factor in preventing maternal deaths and in producing phenomenally low maternal mortality rates.

This is, indeed, a story of human as well as medical progress. The fact that the chances of survival for the mother are better than 999 out of 1,000 should bring comfort and consolation in a troubled era to expectant mothers and their husbands, their children and their parents. Childbearing has been made quite safe.

SPECIALTY JOURNALS OF THE AMERICAN MEDICAL ASSOCIATION

The October numbers of the nine specialty journals of the American Medical Association were published with a number of changes which are intended to identify them more closely with the Association and to help meet certain problems facing these journals. The titles of the publications have been changed to include the designation "A. M. A." as part of the title, so that the new titles appear as, for example, *A. M. A. Archives of Surgery* and *A. M. A. Archives of Internal Medicine.* This change was undertaken after consideration by the chief editors of the journals and their editorial boards and the Board of Trustees.

The primary purpose of the use of the letters A. M. A. is to effect a closer identification of these journals with the American Medical Association in the minds of the readers and others who learn of the journals. Although the explanatory statement "Published monthly by the American Medical Association" appears on the bottom of the cover page, there has been some misunderstanding concerning the sponsorship of these journals. The periodicals are now identified in much the same way as other allied specialty journals are identified with the organization that sponsors them. Consideration was given to the use of the full name of the Association as, for example, "American Medical Association Surgery" and "American Medical Association Archives of Surgery." However, after consultation with librarians, book publishers and others, it was concluded that it was preferable to use the identifying symbol A. M. A.

Concurrently with the change in title, the color of the cover was changed to white with the titles being identified in different colors. An attempt was made to select a color for the title that would match the former color of the cover. This change also was made to indicate the close relation of the specialty journals. In addition, it was believed that there would be an improvement in the appearance—which has been borne out by the comments from other publishers—and permit use of this space for advertising purposes. While the specialty journals are not intended to be a source of profit for the American Medical Association, costs of labor and paper, *to mention just two items, have increased so much in* the past two years that various means had to be sought to meet in part these increased expenditures. The table of contents, which formerly was found on the back cover page, has been moved to the pages immediately preceding the first article or editorial.

These changes were announced to subscribers through a special statement in the September number of each of the journals, and a reference to the change was made in the report of the Board of Trustees in the Oct. 21, 1950, issue of THE JOURNAL. Several inquiries have arisen from libraries regarding the cataloging or indexing of the journals with the new titles. Beginning with volume 49 (January-June, 1951) the *Quarterly Cumulative Index Medicus* will list these journals under the new titles, so that the letters A. M. A. will be considered as an integral part of the titles. For the completion of volume 48 (July-December, 1950) the *Quarterly Cumulative Index Medicus* will continue to use the old titles without the designation A. M. A. The changes were made before the current volume numbers were completed because of certain production difficulties which required a number of changes in October.

ORIGIN OF THE BILE PIGMENTS

One of the most widely accepted statements in basic science medical literature is that the bile pigments are derived from the breakdown of blood hemoglobin. The evidence for this view dates back at least 100 years to the now classic observation of Virchow [1] that the orange pigment, "hematoidin," found at the site of old blood extravasations were similar to bilirubin. Many years later, Hans Fischer and his co-workers [2] conclusively demonstrated that "hematoidin" was identical with bilirubin. Other well known investigators who contributed evidence in support of the above view include Kühne, Herrmann and, more recently in this country, Whipple and his group,[3] who demonstrated that the heme of hemoglobin is almost quantitatively converted to bilirubin in the dog.

Currently, the problem of the origin of the bile pigments is being reinvestigated at Columbia University with the modern isotopic tracer technic. These studies in general confirm the earlier classic view that the bile pigments are derived from destroyed hemoglobin of red cells. Hematin which had been previously "labeled" with isotopic N^{15}, by the administration of glycine containing N^{15}, was found to be readily converted to bile pigment in the dog.[4] The isolated bile pigments were found to contain the isotopic N^{15} derived from the administered hematin. Similar results were obtained in normal human subjects.[5] However, the additional *rather unexpected observation* was made that at least 11 per cent of the bile pigment was derived from sources other than the breakdown of hemoglobin. The normal male subjects were given glycine containing N^{15}. Previous work by this group of investigators has demonstrated that the glycine is incorporated into the heme portion of the hemoglobin molecule. Furthermore, these investigators had shown that the labeled hemoglobin remains in the circulating erythrocytes for approximately 120 days, until the red cell is destroyed. Thus, if bile pigment is derived solely from hemoglobin liberated from destroyed erythrocytes, then no significant amount of N^{15} should be found in the bile pigment until nearly 120 days after the administration of N^{15} labeled glycine. Actually, a prompt and pronounced rise in N^{15} containing bile pigment (stercobilin isolated from the feces) was found. A second, expected rise approximately 100 to 140 days after the administration of the N^{15} glycine was observed. Undoubtedly the labeled bile pigment in this case was derived from the destroyed N^{15} labeled hemoglobin. The early rise in labeled bile pigment was even more pronounced in patients with pernicious anemia [6] and with congenital porphyria.[7] A large part, at least 31 per cent, of the bile pigment, stercobilin, obtained from stools of the latter patient was formed from sources other than the hemoglobin of the mature erythrocyte.

The nature of the unknown precursor of bile pigments has not yet been determined. Several possibilities have been suggested.[5] The "extra" bile pigment may be derived from hemoglobin which has escaped incorporation into erythrocytes, or from myoglobin as suggested years ago by Whipple,[8] or from the cytochromes or catalase, or from porphyrins or heme not utilized for hemoglobin synthesis or perhaps from a direct synthesis of bile pigment not involving the porphyrins. The solution of this problem should add considerably to the understanding of the origin and metabolism of the bile pigments. Thus it appears today that the long-established view that the bile pigments are derived solely from the breakdown of hemoglobin must now be modified to include other, as yet unidentified, probably nonhemoglobin, precursors in normal man and particularly in patients with pernicious anemia and congenital porphyria.

WASHINGTON NEWS

(From the Washington Office of the American Medical Association)

The New Congress

The *Congressional Quarterly*, a legislative information service, concludes that the administration will have six fewer supporters for its domestic policy in the new Senate. Eight senators-elect are listed as certain to oppose Mr. Truman's chief domestic proposals: Richard Nixon (Republican, California), George A. Smathers (Democrat, Florida), Herman Welker (Republican, Idaho), Frank Carlson (Republican, Kansas), Willis Smith (Democrat, North Carolina), James Duff (Republican, Pennsylvania) and Wallace F. Bennett (Republican, Utah). The net loss is expected to be reduced to six because of support for Mr. Truman from Thomas C. Hennings (Democrat, Missouri) and A. S. (Mike) Monroney (Democrat, Oklahoma).

Twenty-three Democratic first-termers elected in 1948 (all mid-westerners) were among that party's 28 House casualities. . . . The Congress actually will not be very "new"; about 85 per cent of the membership served previously in the House or Senate, including 18 out of office during the Eighty-First Congress. . . . Defeat of Representative Vito Marcantonio (American Labor Party, New York) means no minor party representative for the first time in 40 years. . . . Frazier Reams of Ohio, a long time Democrat who won as an Independent, will vote with Democrats on organizing the House, but says he will "remain aloof" from the party. . . . Southerners, as usual, dominate committee chairmanships, with eleven. Incidentally, committee chairmen average six years younger, 60 instead of the 68 of the Eighty-First Congress. . . . Even so, chairmen will average seven years older than the average age for both houses, about 53. . . . Representative Robert L. Doughton (Democrat, North Carolina) continues to hold his title as the oldest member, 87, while the youngest will be reelected Representative Lloyd M. Bentsen Jr. (Democrat, Texas), who will be 29 the day Congress opens. . . . There will be no change among House leaders, but a major reshuffling of Senate leadership will be required because of election defeats. . . . Of the nine representatives who tried for the Senate, four were successful; of five who tried for governor, two lost.

The Present Session of Congress

Theoretically, the present session opening next week could turn its attention to the long list of health bills not passed in the last two years. But practically, this is impossible. Extension of rent controls, new taxes, revision of the antisubversive bill, Alaskan and Hawaiian statehood, defense and other top priority bills should keep House and Senate occupied until time for adjournment in December. When this Congress passes out of existence, it will take with it such unfinished medical legislation as aid to medical education, aid to local public health units, aid to school health programs, national compulsory health insurance and the various plans to stimulate voluntary insurance. However, one can expect to see all these bills come to life again in the new Congress after the first of the year.

Military Notes

Although the Army as a whole has not been able to put into effect the "point system" for release of reserves, its medical department is more fortunate. A spokesman said the Surgeon General's office in most cases still expects to release World War II medical reserves from active duty when they have completed necessary training and when replacements are available. With a steady supply of physicians assured by the doctor-draft, the medical department at the present time is not experiencing the same manpower difficulties as are other branches. But, as usual, it will not be possible to apply the release policy in every case. . . . Deane W. Malott, president of the National Association of State Universities and Association of Land-Grant Colleges, spoke against the proposal to defer high-ranking students in all courses. He advocated that all men be required to serve 18 months to two years at a time of their choice between the ages of 18 and 26. This, he pointed out, would give the military services a variety of professionally trained and skilled men and would lessen the chance of good students rushing to "easy" courses where their grades would be higher. . . . Endorsing a recommendation of Dr. Howard A. Rusk's Committee on Veterans Hospitals, VA Medical Director Dr. Paul B. Magnuson points out that VA has the facilities and beds to care for many of the Defense Department's wounded returned from overseas but that there has been no request for use of these facilities. He mentioned care for amputees, artificial limb service, training and rehabilitation and plastic surgery as specific fields where VA is thoroughly equipped to care for patients. In the absence of a system for transferring patients, he says military services are wasting medical manpower. . . . In another speech recently Dr. Magnuson urged voluntary workers to help VA get rehabilitated men to leave VA hospitals. He warned against turning VA hospitals into "country clubs," where men tend to stay longer than necessary, denying others hospital care.

Deferment of Interns and Residents

In an effort to insure the deferment of interns and residents who are essential to the community welfare in their present positions, Dr. Howard A. Rusk has sent special instructions to state chairmen of voluntary advisory committees. Dr. Rusk, chairman of the National Advisory Committee to Selective Service, emphasized that evidence of essentiality must be presented to the registrant's local board, which is not necessarily located in the same community as the hospital. He asked state chairmen and local committees to "support fully" before local boards any claims of essentiality which may be presented in behalf of a registrant whose hospital is located elsewhere.

Public Health Service Needs Doctors

The Public Health Service, faced with civil defense as well as overseas responsibilities, is finding difficulty in recruiting professional personnel. Although the service has campaigned constantly for physicians, it was able to add only 30 commissioned medical officers to its rolls between July 1 and mid-October. The totals are 1,038 and 1,068. In addition, the Public Health Service has 114 full time Civil Service physicians and 150 part time. The Division of International Health (PHS) at present is attempting to sign up 15 qualified physicians for the ECA program in Indochina, Thailand, Burma and Indonesia. In these areas emphasis will be placed on the prevention and control of tropical diseases. The Public Health Service is in immediate need of three physicians to serve with its mission to Liberia, which operates under State Department funds and also carries on preventive and control activities. In Greece, the Public Health Service has conducted a program for three years, concentrating on hospital rehabilitation, water supply installations, tuberculosis control and nurse training. At least 100 physicians will be needed for foreign service in the next year, when a number of new programs will be set up. Under consideration are projects for Turkey, Iran, Formosa and the Philippines. Although base pay for commissioned officers ranges from $4,500 to $5,500 per year, various allowances more than double the total income. Civil Service appointments carry salaries of $6,400 to $8,800, with 25 per cent additional allowed for service in Southeast Asia and quarters allowances that vary from $2,000 to $2,400.

The Public Health Service is scheduling examinations for assistant surgeons and senior assistant surgeons in the PHS Regular Corps. Examinations will be held throughout the country on Feb. 12, 13 and 14, 1951, but applications must be in by January 15. Applications and information may be obtained from the Surgeon General, U. S. Public Health Service, Federal Security Agency, Washington 25, D. C., Attention: Division of Commissioned Officers.

Survey of Health Services

Directors of the special congressional survey of health services say that information is coming in at a satisfactory pace, but they are not able to say whether a complete report will be ready by next February 1, the deadline set by the Senate Labor and Public Welfare Committee. The survey, to cover state and local health facilities as well as voluntary plans, is being handled by a committee under the chairmanship of Dr. Dean Clark. Blue Cross and Blue Shield organizations expect to turn in information on their operations by December 1, as do commercial insurance companies. Additional data will be supplied on medical plans operated by such nonprofit organizations as cooperatives and labor unions, and A.M.A.'s Chicago headquarters will gather details on medically sponsored programs not under Blue Shield.

Stockpile of Medical Supplies

The federal government again has come under criticism from a New York state official for delay in setting up medical stockpiles under the civil defense program. In approving allocation of $500,000 in state funds for this purpose, Governor Thomas E. Dewey said, "Apparently the federal government not only has no plans but no intention of providing medical supplies, and these, of course, are of first importance." A few weeks ago similar views were expressed by Dr. Herman Hilleboe, New York health officer. In reply, a National Security Resources Board spokesman points out that this agency has neither money nor authority to start regional reserves of medical supplies and equipment. New York and NSRB representatives are expected to meet soon in an effort to reach some agreement on respective responsibilities. Governor Dewey said supplies to be purchased by the state will be mainly drugs and antibiotics, blood transfusion sets, burn and treatment supplies, fracture supplies, syringes and needles and surgical kits.

Food and Drug Administration Convictions

The Food and Drug Administration's report on convictions for October deviates from its usual prosaic style to tell how agents tracked down two herb doctors in the hills of Oklahoma and in Memphis, Tenn. In the first case a Food and Drug inspector visited the "Indian herb doctor" in Oklahoma as a "patient." After looking at the agent's hands and nails, the "doctor" diagnosed the ailment as "sugar diabetes" and prescribed a concoction three times a week. In line of duty the inspector had to gulp down a glass of the stuff. Re-orders of the herbs (in fruit jars with the patient's name the only label) were delivered by "runners," who crossed state lines in private cars. The "Indian herb doctor" was permanently enjoined against interstate shipping and labeling of his wares.

The second case, the "African herb doctor" from Memphis, fined $9,000 and given nine years in prison, concerns a West African who prepares herbs from a book by Dr. Culpepper, an English physician who died in 1640. The "African herb doctor" was not a stranger to the law. Previously, he had been convicted in Michigan, Arkansas and Tennessee for illegal practice of medicine, served a jail term for mail fraud and had signed a Federal Trade Commission stipulation in 1943 to the effect that a hair-growing formula was ineffective. This time he was convicted on 15 counts for shipping four herbal medicines misbranded with false claims.

Elsewhere, 10 druggists were convicted for selling barbiturates and other potent drugs without prescription. There were several other cases of misbranding and shipping faulty products.

Notes

Two new National Advisory Councils, authorized by the last session of Congress, have been set up within the National Institutes of Health. At the time it announced members of the new councils (Arthritis and Metabolic Diseases and Neurological Diseases and Blindness) NIH also announced names of new members appointed to existing councils. Eighteen of the 43 new appointments go to physicians.

Members of the National Advisory Arthritis, Rheumatism and Metabolic Diseases Council are William P. Holbrook, M.D., Tucson, Ariz.; Clyde E. Wildman, president, De Pauw University, Greencastle, Ind.; Weston Howland, head New England chapter of Arthritis and Rheumatism Foundation, Milton, Mass.; C. James Watson, M.D., chairman, Department of Medicine, University of Minnesota, Minneapolis; Philip S. Hench, M.D., chief, Department of Rheumatic Diseases, Mayo Clinic; Floyd B. Odlum, business executive, New York City; Richard H. Freyberg, M.D., associate professor of clinical medicine, Cornell Medical College, New York City; Maxwell M. Wintrobe, M.D., head, Department of Internal Medicine, University of Utah, Salt Lake City, and John A. Reed, M.D., clinical professor of medicine, George Washington University Medical School, Washington, D. C.

Members of the National Advisory Neurological Diseases and Blindness Council are Percival Bailey, M.D., professor of neurology and neurological surgery, University of Illinois Medical College, Chicago; Cecil A. Johnson, lawyer, Chicago; Henry W. Woltman, M.D., chairman, Neurology and Psychiatry sections, Mayo Foundation Graduate School; George Baehr, M.D., professor and director of clinical research, Columbia University; Leonard Goldenson, New York; Dan Gordon, M.D., assistant professor of clinical surgery, Cornell Medical College, New York City; H. Houston Merritt, M.D., director, Neurology Institute, Presbyterian Hospital, New York City; Cornelius H. Traeger, M.D., head, National Society for Multiple Sclerosis, New York; Dilworth W. Woolley, Rockefeller Institute, New York; J. S. Ulmer, lawyer, Cleveland; P. F. Lucchesi, M.D., professor of pediatrics, Temple Medical School, Philadelphia, and W. Kuhn Barnett, educator, Richmond, Va.

Other newly appointed physicians are Robert F. Loeb, recently appointed to the National Science Foundation and professor at Columbia University—appointed to the National Advisory Health Council; Irvine H. Page, director, Cleveland Clinic Foundation, and member of the National Research Council, and Hugh J. Morgan, physician and chief of Vanderbilt University Hospital, Nashville—appointed to the National Advisory Heart Council. William Malamud, professor and head, Department of Psychiatry, Boston University Medical School, and Samuel B. Wortis, director, Psychiatry and Neurological Service, Bellevue Medical Center, New York University—appointed to the National Advisory Mental Health Council.

Each advisory council meets for one or two days quarterly to review applications for grants and make recommendations to the Surgeon General as to which grants should be issued. Grants are previously screened by NIH, but the councils set the priority of grants and the amount to be spent. These grant programs now total about $50,000,000 per year, compared with about $4,000,000 in 1946. Members of the councils meet together once a year to discuss interrelated programs of the various divisions of NIH. They receive $50 per diem while actually engaged in council work but no salary.

GOVERNMENT SERVICES

Army

New Type of Army Medical Company

A preventive medicine unit of company size, first of several of its kind now being organized by the Army Medical Service, has arrived in the Far East Command for duty in Korea, Major Gen. R. W. Bliss, the Surgeon General, has announced.

Successor to the malaria survey and malaria control detachments of World War II, the new company has functions beyond the scope of previous units of this type. In addition to malaria control and survey, the units will be responsible for inspections of field sanitary conditions and control of insect-borne, water-borne and other diseases. When acting in support of combat troops, these companies will operate as far forward as necessary to accomplish their mission.

The new preventive medicine companies are composed of six officers, one warrant officer and 59 enlisted men. Units are being organized at Brooke Army Medical Center, Fort Sam Houston, Texas. Officer personnel are qualified entomologists or sanitary engineers and the enlisted men have had training in one or more phases of preventive medicine. The preventive medicine company is composed of a headquarters section, to accomplish command and administrative work, and a preventive medicine service subdivided into a hygiene and sanitation section, survey section and three control sections.

The hygiene and sanitation section investigates water points, waste disposal, troop shelter, bathing and laundering facilities, mess sanitation, contamination of food or water and adequacy of clothing. The survey section inspects sanitary discipline in other units, determines the incidence and distribution of insect-borne and similar diseases and checks on the origin of cases of these diseases admitted to hospitals in its area. The control section furnishes technical supervision for work details engaged in sanitary control measures, conducts on-the-job training of soldiers in insect and rodent control measures and recommends corrective measures for other units.

Public Health Service

Regular Corps Examination for Medical Officers

An examination for appointment of medical officers in the Regular Corps of the Public Health Service will be held Feb. 12-14, 1951, at points throughout the United States. Applications must be received no later than Jan. 15, 1951. Appointments will be made in the grades of assistant surgeon (equivalent to Navy rank of lieutenant [j.g.]) and senior assistant surgeon (equivalent to lieutenant). Appointments are permanent in nature and provide opportunities to qualified physicians for a career in clinical medicine, research and public health. Applicants who successfully complete this examination may ordinarily expect appointment as soon as they become eligible.

The requirements for both grades are United States citizenship, at least 21 years of age, graduation from a recognized school of medicine and, for assistant surgeon, at least seven years of educational training and professional experience subsequent to high school. For senior assistant surgeon, at least 10 years of educational training and professional experience subsequent to high school are required. Physicians who are successful in the examination and are now serving internships will not be placed on active duty in the Regular Corps until completion of internship.

The examination will include an oral interview, physical examination and written objective tests covering the professional field. The written professional examination for the grade of assistant surgeon will cover basic medical sciences, internal medicine (including neurology and psychiatry), therapeutics and toxicology, pediatrics, and medical problems of obstetrics and gynecology, surgery, orthopedics, gynecology, obstetric procedures, and preventive medicine and public health. The examination for senior assistant surgeon will include the above subjects with the exception of anatomy.

Physical requirements: Candidates must be physically qualified as a result of an examination performed at a Public Health Service facility; it is recommended that applicants complete this examination as soon as possible to obviate the necessity of taking the written examination if found not physically qualified. Candidates who have a physical defect, or who have had serious illness or injury, should attach a statement to their applications outlining in detail the nature of such illnesses or injuries, treatment received, periods of hospitalization, length of absence from work and present status.

Entrance pay for an assistant surgeon with dependents is $5,686.56 per annum, and for senior assistant surgeon with dependents, $6,546. These figures include the $1,200 annual additional pay received by medical officers as well as subsistence and rental allowance. Officers on active duty are not eligible to receive disability compensation from the Veterans Administration. Retirement pay after 30 years of service or at the age of 64 is three-fourths annual basic pay at the time of retirement. Retirement for disability is authorized. Additional benefits include periodic pay increases (time served as a member of the armed forces is credited), 30 days' annual leave, sick leave, full medical care and the usual privileges extended to officers of the military forces. Information may be obtained from the Surgeon General, United States Public Health Service, Washington 25, D. C. Attention: Division of Commissioned Officers.

Air Force

Director of Research

Col. Paul A. Campbell, who recently gave up private practice in Chicago to accept a regular commission in the air force, has returned to the Air Force School of Aviation Medicine, Randolph Air Force Base, Texas, as director of research. For many years he specialized in otolaryngology, which he taught at Rush Medical College, the University of Illinois and Northwestern medical schools. He made his first solo flight 10 years ago. He is program chairman for the Aero Medical Association, has served as medical consultant for United Airlines, senior attending staff surgeon for Wesley Memorial Hospital, Chicago, and consultant for the Air Force Surgeon General. Colonel Campbell has published many articles, papers and has written chapters for medical textbooks. He served in Europe during World War II. His decorations include the Legion of Merit, the Army Commendation Medal and the Royal Order of the Sword of Sweden.

Personal

Col. Robert J. Platt, former surgeon of the Far Eastern Air Force, has been named commandant of the Alabama branch of the Air Force School of Aviation Medicine. The new branch of the Air Force medical school will be located at Gunter Air Force Base, Montgomery, Ala., where all flight nurse and airman training will be conducted. Colonel Platt is a 1927 honor graduate of the School of Aviation Medicine.

MEDICAL NEWS

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

Mental Health Program.—A meeting to activate the newly formed Arizona Association for Mental Health was held November 13 in Phoenix. The organization first came into being at planning sessions held in Phoenix last August 3, when Arizona became the thirty-fourth state to organize a citizen's mental health association.

Further aid in developing a mental health program for the state was made recently by three mothers' clubs of Nogales, which sent a check to the state treasurer to deposit to the account of a special mental health fund for Arizona.

CALIFORNIA

Personal.—Dr. Eugene M. Farber has been promoted to the director of the Division of Dermatology and associate professor of dermatology (medicine) at Stanford University School of Medicine, San Francisco. He is also chief of dermatology at Stanford University Hospitals, San Francisco.

Hospital News.—The new unit of Mount Zion Hospital, San Francisco, which was opened in November, provides over 150 additional beds, making a new total of 325 for the entire hospital. The Harold Brunn Institute for Cardiovascular Research will occupy about 7,000 square feet, in association with cancer and tuberculosis research carried on by staff members.

Basic Science Courses.—St. Mary's Hospital in San Francisco will present basic science courses in applied anatomy and physiology and biochemistry throughout the year The anatomy lectures are being presented by Dr. Harold H. Lindner, lecturer in anatomy and clinical assistant in surgery at the University of California Medical School, Berkeley-San Francisco These lectures are being given on Thursdays from 7:45 p. m. to 9:15 p. m. There will be no lecture the week of Thanksgiving. Subjects of lectures beginning November 30 and for the succeeding weeks through February include the tongue, cervical nerve tracts, prevertebral area of the neck, cervical vertebrae, the axilla, female breast, thoracic wall, mediastinum, lungs and pleura and anterior abdominal wall. The biochemistry and physiology lectures are being given on alternating Saturdays from 9:00 to 10:00 a. m. by Harold A. Harper, Ph.D., lecturer in surgery at the University of California School of Medicine, San Francisco, and director of the chemistry laboratory of the hospital. Beginning with the November 25 lecture, the subjects will be physiology of the kidney, physiological and chemical aspects of shock, physiological basis of liver function tests, enzymes in tissue metabolism and carbohydrate metabolism.

IDAHO

State Association Committees Appointed.—The Idaho State Medical Association's Armed Forces Advisory Committee was elected by members of the component society committees at a meeting in Boise October 21. Dr. Orval F. Swindell, Boise, former president of the association and secretary-treasurer of the Welfare and Grievance Committee, was named chairman. Other members are Drs. Clifford O. Armstrong, Moscow; Fred A. Pittenger, Boise; Charles A. Terhune, Burley, and Harvey E. Guyett, Idaho Falls. Dr. Verne J. Reynolds, Boise, has been appointed chairman of the association's Civilian Defense Committee. Other members include Drs. Judson B. Morris, Boise; Lester L. Shupe, Caldwell; Henry C. Turner, Pocatello; Dauchy Migel, Idaho Falls; Fred T. Kolouch, Twin Falls; James W. Hawkins, Coeur d'Alene; Robert E. Staley, Kellogg, and James H. Bauman, Lewiston.

ILLINOIS

Lake Pollution Suit Ending.—Dismissal of the last defendants in the suit brought by the State of Illinois seven years ago against the State of Indiana and 24 of its cities and industries to compel a halt on Lake Michigan pollution has been recommended to the United States Supreme Court. All the defendents, it is reported, have complied with the court's requirements at a cost of nearly $15,000,000. Pollution was a threat to the metropolitan water supply and recreational areas caused by Indiana's dumping of raw sewage and untreated industrial wastes into Lake Michigan and streams emptying into it. The original suit was filed by the Illinois Attorney General Oct. 9, 1943 against Indiana and the cities of Gary, Hammond, East Chicago and Whiting, and in 1945 twenty industries were added as co-defendants. Thereafter lawyers for both sides stipulated antipollution measures that, when completed, would allow the defendants to be dropped from the suit.

Chicago

Chicago Medical Society.—Two guest speakers will address the Chicago Medical Society at its meeting December 13 at 8:00 p. m. in the John B. Murphy Memorial Auditorium. Dr. Perrin H. Long, Baltimore, will speak on "Current Clinical Usage of Antibiotics," and Comdr. Thomas J. Canty (MC, USN), Oakland, Calif., on "Amputation Surgery and Recent Developments in Artificial Limbs."

Institute of Medicine Annual Meeting.—Dr. Stanley Gibson, professor of pediatrics emeritus, Northwestern University Medical School, will deliver the presidential address at the thirty-fifth annual meeting of the Institute of Medicine of Chicago December 5 at the Furniture Club of America. His subject will be "Diagnosis of Congenital Cardiovascular Anomalies Amenable to Surgery."

Ophthalmological Society Prize.—The Chicago Ophthalmological Society announces that friends of the late Dr. Louis Bothman have contributed money through his medical fraternity, Phi Delta Epsilon, for a yearly prize of $100 for the best paper submitted to the society by an ophthalmologist who has completed his training within the previous six years. Such paper may be used as an entrance thesis for membership in the society. Papers for the first award should be submitted to the secretary of the society, Dr. Gail R. Soper, 636 Church Street, Evanston, Ill., not later than July 1, 1951.

INDIANA

Monthly Series of Telephone Seminars.—The Indiana University School of Medicine, with the cooperation of the Indiana State Medical Association, has scheduled a monthly series of telephone seminars in postgraduate medical education, which will be carried by leased wires to gatherings of physicians throughout the state. The first of these was presented November 7. Success of a test program from the auditorium of the medical school by closed telephone circuit to a meeting of the St. Elizabeth hospital staff in Lafayette led to endorsement of the program by the medical school council and the committee on medical education of the state association. Fifteen county societies listened in on the program. This method permits the local doctors of the county to attend these meetings without the necessity of long and hazardous driving in winter months and also makes it possible for speakers to make their comments without unnecessary driving. The flexibility of this plan makes the most outstanding experts in all fields of medical science available to the entire profession of Indiana. To enable listeners to receive the full value from the telephone program there will soon be available to each physician a listing in a brochure carrying a picture of the speaker with a biographical sketch, an outline of his remarks, together with any reproductions of illustrations or charts he might normally use in his presentation. It is hoped that before long every county society within the state will be participating in the program.

KENTUCKY

Exhibit Wins Award.—A silver award from the American Roentgen Ray Society was given to an exhibit presented by the department of radiology at Veterans Administration Hospital and the University of Louisville School of Medicine. The exhibit on abdominal aortography showed new uses and possibilities in the technic. Dr. David Shapiro, chief radiologist at the hospital and assistant professor of radiology at the medical school, and Drs. Joseph C. Bell, Everett L. Pirkey, and Gerald M. Peterson, physicians on the faculty of the medical school, prepared the display.

MASSACHUSETTS

Tufts Alumni Lecture.—The annual medical alumni lecture will be given by Dr Frederick W. Maroney, Brooklyn College, New York, December 5 at 8 00 p m at the Tufts College Medical School, Boston on "Protect the Power House" This lecture is given annually by a distinguished alumnus of the medical school who is not on its faculty. Physicians, students and the faculty of Tufts College Medical School are invited

Clinical Anesthesiology.—A new program in clinical anesthesiology is being offered by Boston University School of Medicine under Dr Julia G Arrowood, professor of anesthesiology The course is designed for physicians practicing anesthesia in community hospitals Clinical facilities for the course have been made available at Massachusetts Memorial Hospitals Students are admitted as full time members of the resident staff for three months They are guided in preoperative and postoperative care of the patient as well as in administering anesthesia for clinical surgery They participate in clinics and conferences and may prepare for examinations of the American Board of Anesthesiology No fees are required Clinical facilities limit the enrolment to two students at a time

MICHIGAN

State Medical Election—The newly elected officers of the Michigan State Medical Society are Dr Clarence E Umphrey, Detroit president, Dr Otto O Beck, Birmingham, president-elect, Dr L Fernald Foster, Bay City, secretary, and Dr Andrew S Brunk, Detroit, treasurer

Public Health Conference—The thirtieth annual Michigan Public Health Conference will be held in the Pantlind Hotel and Civic Auditorium, Grand Rapids, November 29 December 1 to consider "New Weapons in the Battle Against Disease" and the role of public health personnel in civil defense and in time of disaster Physicians interested are cordially invited to attend the conference sessions Copies of the program may be obtained from the Michigan Department of Health, Lansing

MINNESOTA

Personal.—The Republic of Syria has sent to Dr Khalil G Wakim, Rochester, the medal of highest order of merit in appreciation of his services to the medical school of the National University of Syria in Damascus At the request of the Syrian government Dr Wakim was sent by the State Department in Washington to give lectures and help reorganize the medical school

Course in Obstetrics.—A continuation course in obstetrics for general physicians will be presented at the University of Minnesota, Minneapolis, December 15 and 16 Visiting faculty members for the course will include Dr Emil G Holmstrom, University of Utah School of Medicine Salt Lake City, Dr Curtis J Lund, Louisiana State University School of Medicine, New Orleans, and Dr Charles E McLennan, Stanford University School of Medicine, San Francisco

NEBRASKA

Carey Memorial Lecture.—The third annual Dr Eben J. Carey Memorial Lecture will be delivered November 27 at 8 00 p m in the Joslyn Memorial Art Museum Lecture Hall at Omaha by Dr C Rollins Hanlon, head of the department of surgery, St Louis University School of Medicine, on "Surgical Treatment of Cardiovascular Disease" This lecture is sponsored by Creighton University and the Phi Chi Medical Fraternity. Previously Dr Hanlon was associate professor of surgery at Johns Hopkins University Preceding the lecture Dr Hanlon will be entertained at a dinner at the Omaha Athletic Club by the Phi Chi Medical Fraternity Dr Carey, in whose memory these lectures are given, was at the time of his death dean of the Marquette University School of Medicine, Milwaukee For many years he had held a national office in the Phi Chi Medical Fraternity.

NEW YORK

Allergy Society Lecture.—Dr Carl E Arbesman, instructor in bacteriology and immunology, University of Buffalo School of Medicine, will speak on "Testing and Newer Therapy in Asthma and Hay Fever" at a meeting of the Allergy Society of Syracuse November 29 at 8 30 p m at University Hospital. The lecture has been arranged by the Medical Society of the State of New York in cooperation with the New York State Department of Health

Incidence of Cerebral Palsy—The number of persons handicapped by cerebral palsy annually is more than twice the number who are moderately or severely handicapped as a result of poliomyelitis, according to Dr I Jay Brightman, Albany, assistant commissioner for medical services of the New York State Department of Health He told the meeting of the New York State Association for Crippled Children that cerebral palsy occurs in about six patients in every 1,000 births, which in New York means 1,500 new cases per year Of these, 100 have minor involvement and 200 die early in life Thus the total of cerebral palsied added to the population is 1,200 or more It was reported that New York City will open two classes for cerebral palsied in Public School 85, the Bronx, and plans are under way for a similar unit on Staten Island

Academy Programs.—The Rochester Academy of Medicine has arranged the following programs for its Tuesday evening (8 30) monthly meetings

Dec 5, D Gordon Murray, Toronto, Canada, Surgery of Congenital Heart Disease
Jan 9 Joe W Howland Rochester, N Y, moderator, Symposium on Medical Problems in Atomic Energy
Feb 6, Hugh McCulloch, Chicago, Recent Advances in Rheumatic Fever
March 6 Philip S Hench Rochester Minn, Uses of ACTH
April 3, Edith H Quimby, Sc D, New York, Clinical Uses of Radioactive Isotopes

New York City

Panel on Pulmonary Tuberculosis.—The Tuberculosis Sanatorium Conference of Metropolitan New York will hold its clinical session on chronic pulmonary disease November 29 at 8 15 p m in the Cornell University Medical College Amphitheatre There will be a panel discussion on the "Correlation of Pathological, Clinical and Roentgenologic Findings in Patients with Pulmonary Tuberculosis Having Lung Resection"

Infant Mortality Committee Program.—The special committee on infant mortality of the Medical Society of the County of New York is continuing its monthly meetings open to all members of the medical and nursing profession and medical students Meetings are held in the Academy of Medicine Building the first Wednesday of each month at 8 30 p m At the first meeting, November 1, Dr Louis M Hellman, Baltimore, spoke on "Prevention of Prematurity" The next five lectures are

Dec 6, Priscilla White, Boston, Treatment of the Diabetic Mother and Her Newborn Child
Jan 3, Rustin McIntosh, New York The Pediatrician s Responsibility to the Newborn During the First Seven Days of Life
Feb 7, Bronson Crothers, Boston Neurological Problems of the Neonatal Period
March 7, R Gordon Douglas, New York and Charles A Weymuller, Brooklyn, Obstetrical Anesthesia and Analgesia as It Affects Neonatal Mortality
April 4 Edith L Potter, Chicago Atelectasis in the Newborn

Expand School Health Service.—School health services have been extended to five additional academic high schools as part of the city health department's work The department now gives school health services in 18 academic high schools with a school population of 56,000 and 31 vocational high schools with 45,000 pupils, in addition to the services which it has long given in the elementary parochial and public schools Services are given in 646 elementary public schools with a registration of 655,000 and 340 elementary parochial schools with 230,000 pupils During the 1949-1950 school year the department of health conducted 6,005 doctor sessions in the high schools and nurses spent 47,117 nursing hours at work in high schools The department also conducted 39,008 examinations of pupils in its general health supervision work, of that number 20,653 required further follow-up and study During the year 25,138 students were referred to school physicians or nurses because of either illness or accidental injury Private physicians examined and reported on 16,089 students, of these 2,535 required further follow-up study and care

OHIO

Dr. Derryberry Receives Prentiss Award—C Mayhew Derryberry, Ph D chief, division of public health education, U S Public Health Service, was awarded the Elisabeth Severance Prentiss National Award in Health Education at the tenth anniversary civic luncheon of the Cleveland Health Museum November 13 Given annually since 1944 by the Cleveland Health Museum, the award serves a dual purpose (1) to honor the memory of the museum's first foundation benefactress and (2) to encourage, through recognition, outstanding work in the field of health Dr Derryberry is one of the early proponents of new types of discussion technics Under his leadership the Health Education Section, U S Public Health Service, has become a strong administrative unit He was associate director of research, American Child Health Association, 1933-1935, research assistant, New York University, 1932-1936, and since 1936 has been with the Public Health Service He has been devoted to improvement of technics of health education Previous recipients of the award were Dr Harry E Kleinschmidt, retired master craftsman in health education mediums, 1949, Dr. Donald B Armstrong, Metropolitan Life Insurance Co, 1948, Dr. W. W. Bauer, American Medical Association, 1947; Mary P. Connolly, University of Michigan, 1946; Charles E. A. Winslow, Ph.D., Yale University, 1945, and Mary S. and Evart G. Routzahn, Russell Sage Foundation, 1944.

PENNSYLVANIA

Benjamin Rush Awards.—The Medical Society of the State of Pennsylvania presented these awards during its one hundredth annual session in October in Philadelphia. Leroy Mikels of Stroudsburg, Monroe County, was selected as "the outstanding lay individual who contributed most to the advancement of public health and to the improvement of health conditions in his respective community" during the past year. The Trexler Foundation of Allentown, Lehigh County, received the award as "the outstanding lay organization of Pennsylvania which did most to advance public health and to improve health conditions in the area it serves" during the past year. The winning counties' nominees were among 34 selected by the 22 component societies for the state awards.

Mr. Mikel financed, and guided through the depression years of the thirties, Monroe County's first bedside nursing service. During the past year the Red Cross Public Health Nursing Service, organized and financially helped by him, made 18,000 visits to Monroe County families. He organized in 1949 the voluntary public Blood Donor Program, which provides free blood and plasma to county residents. He was chairman of the American Red Cross Chapter in the Poconos from 1929 to 1947.

The Trexler Foundation, established in 1934, is a privately endowed organization that yearly allocates about $250,000 "for the support of community health organizations and programs, for recreational facilities that support health, and for youth agencies that teach and encourage healthful living and good citizenship" within Allentown and Lehigh County.

Philadelphia

Hospital Residents Banquet.—The sixty-fourth annual banquet of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held December 5 at 7:00 p. m. at the Penn-Sheraton Hotel. Reservations may be had by writing to the secretary-treasurer: Dr. Robert C. McElroy, Room 514, 133 South Thirty-Sixth Street, Philadelphia 4.

Hospital Begins 40 Hour Week.—All employees, including 54 nurses and the century-old Woman's Medical College of Pennsylvania and its hospital, went on a 40 hour week beginning November 13. It is the first hospital in the city to adopt the standard industrial work week across the board. In some cases, particularly among nursing personnel, the new policy means a reduction in weekly work hours of as much as 17 per cent. More than 200 employees are affected. The step was taken, said a spokesman for the college and hospital, mainly to halt the siphoning of skilled employees into industry and business and thus to cut down expensive and crippling turnover in jobs.

GENERAL

Rockefeller Resigns as Institute Head.—John D. Rockefeller Jr. has resigned as president of the Board of Trustees of the Rockefeller Institute for Medical Research and was succeeded by his youngest son, David. Mr. Rockefeller will continue as a member of the board, with which he has been associated since its founding by his father in 1901. David Rockefeller is director of the Carnegie Endowment for International Peace, second vice president of the Chase National Bank and a trustee of the University of Chicago.

Society Election.—At the meeting of the International Union Against Tuberculosis, which was held in Copenhagen, Denmark, September 3-6, Prof. K. A. Jensen of Copenhagen assumed office as president; Dr. Manoel de Abreu of Rio de Janeiro was made president-elect; Prof. Etienne Bernard of Paris was reelected secretary-general, and M. Mirabaud of Paris was elected treasurer. The Twelfth Conference of the International Union Against Tuberculosis will be held in Rio de Janeiro in July or August 1952.

Plastic Surgeons Meeting in Mexico.—The American Society of Plastic and Reconstructive Surgery will hold its annual meeting at the Hotel Del Prado, México, D. F., November 26-29, under the presidency of Dr. Leon E. Sutton, Syracuse, N. Y. The society has been invited to attend the meetings of the Plastic Surgery Section of the IX Asamblea Nacional de Cirujanos, which has arranged preconvention activities. Dr. G. Sanvenero-Roselli, Milan, Italy, has been invited to speak. His subject will be "Congenital Malformations of the Face."

Harriman to Head Red Cross.—E. Roland Harriman, vice chairman of the board of governors, has been appointed by President Truman to succeed General George C. Marshall as president of the American Red Cross December 1. Mr. Harriman was chairman of a committee that planned the reorganization of the Red Cross and was manager of the organization's North Atlantic area during the war. He is also chairman of the Board of Directors of the Union Pacific Railroad. General Marshall was appointed president of the Red Cross on Sept. 22, 1949 and has continued to serve in that capacity since his recent appointment as defense secretary.

Markle Foundation Report.—The John and Mary R. Markle Foundation granted more than $800,000 to medical schools and other educational institutions in the year ending June 30, according to the annual report released in October. Of the grants, $500,000 went to medical colleges in the United States and Canada to help young faculty members become established in academic medicine, part of a five year program to build up teaching and research staffs of the schools. Twenty medical schools received $25,000 each for this purpose. Other grants included $110,000 to the Association of American Medical Colleges for research in medical education, $100,000 to the Social Science Research Council and a like amount to the American Council of Learned Societies.

Western Surgical Association.—This association will hold its annual meeting November 29 to December 2 at the Radisson Hotel in Minneapolis under the presidency of Dr. Warren H. Cole, Chicago. Invited speakers include:

Robert P. Meyer, Robert W. Ehrlich, C. Bruce Taylor and John M. Dorsey, Chicago, Experimental Bronchotracheal Anastomosis.
Thomas C. Douglass, W. Harrison Mehn, Benjamin F. Lounsbury, LaVern L. Swigart and Carlos Tanturi, Chicago, Attempts at Experimental Production of Portal Hypertension.
Donald E. Preshaw, Alfred M. Large and Arthur F. Johnson, Detroit, Effect of Portacaval Venous Shunt on Sulfobromophthalein Retention.
Charles S. Rife, Milwaukee, Benign Duodenal Colic Fistula.
Harold Laufman, Frederick W. Preston and Robert V. Bourdeau, Chicago, Efficacy of Hemostatic Agents in the Presence of Anticoagulant Therapy.
Walter R. Stager, Omaha, Bloodshed Conservation and Autotransfusion.

The annual dinner will be held December 1 after a cocktail hour at 6:30 p. m.

Radiological Society Meeting.—The Radiological Society of North America, Inc., will hold its annual meeting December 10-15 at the Palmer House, Chicago, under the presidency of Dr. Warren W. Furey, Chicago. Those presenting papers by invitation include:

Bronson S. Ray, Howard S. Dunbar and Charles T. Dotter, New York, Dural Sinus Venography.
Joseph Hanelin and William R. Eyler, Boston, Pulmonary Artery Thrombosis: Roentgen Manifestations.
Russell Wigh and Frederick R. Gilmore, Philadelphia, Solitary Pulmonary Necrosis: Comparison of Neoplastic and Inflammatory Conditions.
Janet E. Towne and Charles J. Smith, Chicago, Indications for Surgical Intervention in Carcinoma of the Cervix.
Dallas B. Phemister, Chicago, Multiple and Solitary Infarction of Bone in Adults.
Joseph B. Kirsner and Walter L. Palmer, Chicago, Reversibility in Ulcerative Colitis; Clinical and Roentgenologic Observations.
Joseph L. Morton, George W. Callendine, M.S., William G. Meyers, Ph.D., Columbus, Ohio, The Co^{60} Nylon Thread, a New Interstitial Radiation Therapy.
Herbert C. Allen Jr., Raymond L. Libby, Ph.D., Benedict Cassen, Ph.D., Los Angeles, The Scintillation Counter in Clinical Studies of Human Thyroid Physiology Using I^{131}.
George E. Moore and Richard B. Bridenbaugh, Minneapolis, Roentgen Demonstration of the Venous Circulation in the Liver Portal Venography.
Charles B. Huggins and E. V. Jensen, Ph.D., Chicago, Plasma Proteins in Cancer.

A series of refresher courses will be presented beginning with two on Sunday and seven courses daily from 8:30 to 10 a. m. Nonmembers will be charged a fee for the courses. Both scientific and commercial exhibits will be shown. The Carman Lecture will be given Tuesday evening at 8:00 p. m. by Dr. Furey on "The Development of Cardiovascular Radiology." The annual banquet will be held Thursday at 7 p. m.

Prevalence of Whooping Cough.—According to the U. S. Public Health Service, although the week ended November 11 is near the seasonal low week for whooping cough, more new cases of this disease were reported than any other of the common diseases of childhood. A total of 1,780 cases was reported as compared with 1,504 for the same week in 1949, and the 5-year median was 1,863 cases. The cumulative total since the seasonal low week, which falls between September 27 and October 3, is 9,374 as compared with 8,657 for 1949. The cumulative total for the "disease" year 1949-50 which ended September 30 was 118,731, which is more than double the total for the previous year, when 56,635 cases were reported. Estimated mortality rates based on a 10 per cent sample of deaths for the first 8 months of 1950 was 0.8 per 100,000 population, which was 60 per cent higher than that for a similar period in 1949.

AAAS Cleveland Meeting.—The annual meeting of the American Association for the Advancement of Science will be held in Cleveland December 26-30. All 17 of the association's sections and subsections and about 40 scientific societies will hold more than 200 sessions in the Public Auditorium and downtown hotels—Statler, Hollenden, Carter and Allerton. Programs of particular interest to those in the fields of medicine and experimental biology include:

- Section C—Chemistry. Two, of the 12 sessions, on steroid hormones, December 28, a. m. and p. m.; one on medicinal chemistry, evening of December 29.
- Subsection Nm—Medicine. Four session symposium on Biological Effects of Radiation, December 29 and 30, a. m. and p. m.
- Subsection Np—Pharmacy, jointly with the American Pharmaceutical Association, Scientific Session, December 28 and 29.

Information may be obtained from Dr. R. L. Taylor, Assistant Administrative Secretary, AAAS, 1515 Massachusetts Ave., N. W., Washington, D. C.

LATIN AMERICA

Postgraduate Short Course in Cuba.—This course will be presented December 4-6 at the Liceo de Camaguey under the auspices of the Colegio Médico de Camaguey and the Sociedad de Estudios Médicos y Quirurgicos de Camaguey. It will consist of medical lectures given in English and translated into Spanish, lantern slides and discussions. John Elliot, Sc.D., and Dr. Carlos A. P. Lamar, Miami, Fla.; Drs. Robert B. Greenblatt, Augusta, Ga.; E. Perry McCullagh, Cleveland, and Henry H. Turner, Oklahoma City, will be the lecturers. Their subjects will be endocrine problems in childhood, diagnosis and treatment; testicular dysfunction; ovarian dysfunction; blood transfusion; metabolism of carbohydrates; Selye's syndrome of alarm; shock; thyroid disorders; toxic hyperthyroidism treatment; cortical hyperadrenalism; Rh factor; cancer of the breast; hormonal treatment; syndrome of pale large ovaries; sexual maladjustment in married couples, diagnosis and treatment. Further information may be obtained from Colegio Médico de Camaguey, Camaguey, Cuba.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS

Alabama: Montgomery, June 26 28. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Colorado:* Denver, Jan. 3 5, 1951. Exec. Sec., Mrs. B. M. Hudgens, 831 Republic Bldg., Denver.

Delaware: Dover, Jan. 9 11. *Reciprocity.* Jan. 18, 1951. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia:* *Reciprocity.* Washington, Dec. 11. Sec., Dr. Daniel L. Seckinger, 4130 E. Municipal Bldg., Washington.

Florida:* Jacksonville, Nov. 26-28. Sec., Dr. Homer Pearson, 701 Dupont Bldg., Miami.

Georgia: Atlanta, June. Augusta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Ex. Sec., Dr. John Y. Battenfield, Agana.

Hawaii: Honolulu, Jan. 8 11, 1951. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, Jan. 8, 1951. Sec., Mr. Armand L. Bird, 305 Sun Bldg., Boise.

Illinois: Chicago, Jan. 9 11. Superintendent of Registration, Mr. Charles F. Kervin, Capitol Bldg., Springfield.

Indiana: Indianapolis, June 20 22. Exec. Sec., Miss Ruth V. Kirk, 1138 K. of P. Bldg., Indianapolis 4.

Iowa: *Written.* Des Moines, Dec. 4 6. Acting Director, Dr. Walter L. Bierring, Division of Examination and Licensure, State Department of Health, 1027 Des Moines St., Des Moines.

Kansas: Topeka, Dec. 13 14. Sec., Dr. O. W. Davidson, 772 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 11-13. Sec., Dr. Bruce Underwood, 620 South Third St., Louisville.

Louisiana: New Orleans, Dec. 7-9. Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

Maryland: Baltimore, Dec. 12 15. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1. *Homeopathic.* Baltimore, Dec. 12 13. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Massachusetts: Boston, Jan. 23 26, 1951. Sec., Dr. Geo. R. Schadt, 37 State House, Boston.

Minnesota:* Minneapolis, Jan. 16 18. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: Jackson, December. Asst. Sect., Dr. R. N. Whitfield, Jackson 113.

Montana: Helena, April 2 4. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* June 1951. Director, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln.

New Hampshire: *Examination.* Concord, March 14-15. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New York: *Examination.* Albany, Buffalo, Syracuse and New York City, Jan. 30 Feb. 2. Sec., Dr. Jacob L. Lochner, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity.* Winston Salem, Jan. 15. Sec., Dr. Joseph J. Combs, 419 Professional Bldg., Raleigh.

North Dakota: Grand Forks, Jan. 3 6. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: Columbus, December. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* *Examination.* Oklahoma City, June 6 7. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, January 4-6. Sec., Mr. Howard I. Bobbit, 608 Failing Bldg., Portland 4.

Pennsylvania: Philadelphia, January 1951. Acting Secretary, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: Examination. Santurce, March 6. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

Rhode Island:* Providence, Jan. 4 5. Chief, Division of Profesional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota:* Jan. 15-16. Sioux Falls, South Dakota. Sec., Dr. C. E. Sherwood, 109 Center St., West, Madison.

Tennessee:* *Examination.* Memphis, Dec. 21-22. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Utah: Salt Lake City, July 1951. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Vermont: Burlington, February 1951. Sec., Dr. F. J. Lawliss, Richford.

Virginia: Richmond, Nov. 30, Dec. 1-2. Sec., Dr. K. D. Graves, 631 First St., S. W., Roanoke.

Washington:* *Seattle, January 1951.* Sec., Mr. *Edward C. Dohm,* Department of Licenses, Olympia.

West Virginia: Charleston, Jan. 8 10. Sec., Dr. N. H. Dyer, State Capitol, Charleston 5.

Wisconsin:* River Falls, Jan. 9-11, 1951. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

Wyoming: *Examination.* Cheyenne, Feb. 5. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, Dec. 19. Sec., Mr. Francis A. Roy, Room 423, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Dec. 6 7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

Connecticut: *Examination.* Feb. 10. Executive Asst., State Board of Healing Arts, Mr. M. G. Reynolds, 110 Whitney Ave., New Haven 10.

Michigan: *Examination.* Detroit and Ann Arbor, Jan. 12 13. Sec., Miss Eloise LeBeau, 101 No. Walnut St., Lansing 15.

Minnesota: *Examination.* Minneapolis, Jan. 2 3. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Jan. 9 10. Dir., Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, Dec. 10. Sec., Mrs. Marguerite Cantrell, P. O. Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, March 27. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 2. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

South Dakota: *Vermillion, Dec. 1-2.* Sec., *Dr.* Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Memphis, Dec. 27-28. Sec., Dr. O. W. Hyman, 874 Union Avenue, Memphis.

Washington: Seattle, January 1951. Sec., Mr. Edward D. Dohm, Department of Licenses, Olympia.

Wisconsin: *Examination.* Milwaukee, Dec. 2. Madison, April 7. Sec., Mr. W. H. Barber, Scott and Watson Sts., Ripon.

Coming Medical Meetings

American Medical Association, Clinical Session, Cleveland, Dec. 5-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 2-7. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland, Secretary.

American Association of Medical Clinics, Hotel Cleveland, Cleveland, Dec. 4. Dr. Arthur H. Griep, Welborn Clinic, Evansville, Ind., Secretary.

American Psychoanalytic Association, Waldorf-Astoria Hotel, New York, Dec. 7-10. Dr. LeRoy M. A. Maeder, 1910 Rittenhouse Square, Philadelphia 3, Secretary.

American Society of Plastic and Reconstructive Surgery, Mexico City, Mexico, Nov. 27-29. Dr. Clarence R. Straatsma, 66 E. 79th St., New York City, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 13-17. Dr. Victor J. Montilla, P. O. Box 3866, Santurce 29, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 10 15. Dr. Donald S. Childs, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

Southern Surgical Association, Hollywood Beach Hotel, Hollywood, Fla., Dec. 5 7. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Western Surgical Association, Minneapolis, Nov. 30 Dec. 2. Dr. Michael Mason, 154 E. Erie St., Chicago, Secretary.

DEATHS

Kully, Herman Edward ⊕ Omaha, born in Omaha Nov 21 1903, Creighton University School of Medicine Omaha, 1929, assistant professor of otolaryngology and had been acting director of the department at his alma mater, specialist certified by the American Board of Otolaryngology, fellow of the American College of Surgeons, member of the American Academy of Ophthalmology and Otolaryngology, affiliated with Creighton Memorial St Joseph's Hospital, Children's Memorial Hospital Doctors Hospital, Lutheran Hospital and Douglas County Hospital, otolaryngological consultant for the Union Pacific Employees Hospital Association, died September 19, aged 46, of coronary thrombosis

Norris, Samuel Royall, Jacksonville, Fla , born in Raleigh, N C, Feb 7, 1897, University of Pennsylvania School of Medicine, Philadelphia, 1922, specialist certified by the American Board of Obstetrics and Gynecology, member of the American Medical Association, member and past president of the South Atlantic Association of Obstetricians and Gynecologists, past president of Duval County Medical Society, fellow of the American College of Surgeons, affiliated with St Luke's, Riverside and Duval County hospitals, served during World War I, died September 21, aged 53, of lymphosarcoma

Dalton, Richard Andrew Jr , Lafayette, La , Louisiana State University School of Medicine, New Orleans 1944 served as assistant surgeon in the U S Public Health Service Reserve and as a resident in internal medicine at the U S Marine Hospital in Staten Island N Y , drowned while fishing at Grand Isle August 5, aged 30

Eudy, William Thomas, Eminence, Mo , University of Louisville (Ky) Medical Department 1909 member of the American Medical Association secretary of Carter Shannon Counties Medical Society , served overseas during World War I , died in Poplar Bluff (Mo) Hospital September 10 aged 75, of coronary heart disease

Goodrich, Edson Everett, Rome, N Y , Baltimore University School of Medicine, 1900, served on the Mexican Border and overseas during World War I for many years a physician to governmental branches in France, died September 9, aged 73

Guntzer, Germaine Agatha, Honolulu Hawaii Cornell University Medical College, New York, 1931, died September 2, aged 50

Johnson, Nimrod August, Santa Monica Calif , University of Minnesota College of Medicine and Surgery Minneapolis, 1905, member of the Minnesota State Medical Association fellow of the American College of Surgeons, formerly practiced in Minneapolis where he was affiliated with Deaconess and St Mary's hospitals died in Minneapolis September 6, aged 69, of coronary thrombosis

Lamb, Charles W., ⊕ Forest Park Ill , Jenner Medical College, Chicago, 1910, died September 11, aged 71, of carcinoma of the tongue

Miller, Albert Winters, Indianapolis, University of Indianapolis Medical Department, 1903, member of the American Medical Association, served as school physician, affiliated with St Francis Hospital in Beech Grove, died September 12, aged 71, of cerebral hemorrhage

Neergaard, Fred Adolph, Harriman Tenn , Maryland Medical College, Baltimore, 1908 member of the American Medical Association, past president of the Roane County Medical Society , formerly vice president of the Tennessee State Medical Association, served overseas during World War I, affiliated with Harriman Hospital, died in Kingston September 15, aged 67, of acute coronary occlusion

Nelson, Francis Medard, Oakland, Calif , Flint Medical College of New Orleans University, New Orleans, 1904, a medical examiner during World War I, Congressional medalist as examiner for Selective Service System during World War II, died September 6 aged 71, of cerebral accident

Oman, Elmer Samuel, Columbus Ohio, Ohio Medical University, Columbus, 1898, died September 13, aged 82, of cerebral hemorrhage

Purnell, James D., Myrtle, Miss , University of Tennessee Medical Department, Nashville, 1892, member of the American Medical Association, died in New Albany September 13, aged 82

Ravdin, Marcus ⊕ Evansville, Ind , Memphis, (Tenn) Hospital Medical College, 1900, an Associate Fellow of the American Medical Association, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, specialist certified by the American Board of Ophthalmology and American Board of Otolaryngology, consulting oculist Louisville and Nashville Railroad, on the staffs of St Mary's Hospital and Deaconess Hospital, where he died September 12, aged 84, of heart disease

Richey, Clifford Otto, Evansville Ind , Indiana University School of Medicine, Indianapolis, 1922 member of the American Medical Association, served during World Wars I and II, died in the Veterans Administration Hospital, Indianapolis, September 8, aged 51, of hypertensive cardiovascular disease.

Solley, Fred Palmer, New York, College of Physicians and Surgeons, medical department of Columbia College, New York, 1892, formerly on the faculty of his alma mater, past vice president of the New York Academy of Medicine, member of the American Medical Association, served on the staffs of the Knickerbocker Hospital Presbyterian Hospital and St Luke's Hospital, where he died September 7, aged 83, of aplastic anemia

Spackman, Ross Hugh, New York University of Toronto Faculty of Medicine, Toronto, Ont , Canada 1928, member of the American Medical Association, served during World War II, died September 6, aged 48

Spears, Tunis R , Washburn, Wis , Rush Medical College, Chicago, 1889, health officer of Washburn for many years physician for the Omaha Railway, died September 7, aged 87, of heart disease

Speed, George William, Mullens, W Va , University of Cincinnati College of Medicine 1935, member of the American Medical Association, served during World War II, affiliated with Mullens General Hospital formerly on the staff of Madison (W Va) General Hospital, died in Raleigh General Hospital, Beckley, September 10, aged 42, of acute pancreatitis

Squires, Frederick Eugene, Livonia N Y , University of Buffalo School of Medicine 1896, member of the American Medical Association, for many years town health officer died in Strong Memorial Hospital, Rochester September 13 aged 85

Stein, Elias, Flushing, N Y Long Island College of Medicine, Brooklyn 1933, served during World War II, died October 4, aged 40, of heart disease

Sterrett, William John, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh 1901, member of the American Medical Association, for many years trustee of Geneva College, veteran of the Spanish American War served on the Mexican border and during World War I affiliated with Allegheny General Hospital, where he died September 5, aged 76

Swayze, Henry Yandell, Center Point, Texas, Medical Department of Tulane University of Louisiana New Orleans, 1893 fellow of the American College of Chest Physicians, served as superintendent of the Kerrville State Sanatorium in Kerrville, died August 30, aged 80 of heart failure

Talbot, John ⊕ Portland, Ore , College of Physicians and Surgeons of San Francisco, 1916 died August 31, aged 73

Taub, Israel Zangwill, New York, Northwestern University Medical School, Chicago, 1928, died in the Veterans Administration Hospital September 3, aged 57, of uremia

Terry, Marcus Claude, Palo Alto, Calif , Keokuk (Ia) Medical College, 1897, Rush Medical College, Chicago, 1899, served during World War I, served on the staffs of various Veterans Administration hospitals, formerly clinical instructor of immunology at Leland Stanford Junior University School of Medicine, died in Salem, Ore, September 9, aged 79, of acute coronary occlusion

Tinsley, Jack Byrd, Bethlehem Pa , Jefferson Medical College of Philadelphia, 1949, served during World War II, medical resident physician at St Luke's Hospital, where he had been an intern and where he died September 6 aged 28, of lymphatism, blood transfusion reaction and secondary anemia

Turner, Henry William Biddle ⊕ Lieutenant Commander, U S Navy, retired, Miami, Fla , University of Pennsylvania Department of Medicine, Philadelphia, 1906, entered the Medical Corps of the U S Navy as a lieutenant (jg) on July 30, 1908, placed on the retired list Nov 1, 1930, after 22 years' naval service, died near Beaufort, S C, August 3, aged 65, of injuries received in an automobile accident

Utter, Henry Abraham, Harrisburg, Ill , University of Arkansas School of Medicine, Little Rock 1936, died August 19, aged 40, of heart disease

---

⊕ Indicates Fellow of the American Medical Association

ITALY

(From a Regular Correspondent)

FLORENCE, Sept. 10, 1950.

Chronic Polyarthritis

Professor Rietti reported in a session of the Academy of Sciences of Ferrara his observations on 15 patients with primary chronic polyarthritis treated by the method of Lewin and Wassen. The method consists in the simultaneous injection of 5 mg. of desoxycorticosterone acetate intramuscularly and 1 Gm. of ascorbic acid intravenously. Results were favorable only in some cases. The speaker reported that this method is in conflict with experimental researches by Selye, but, from the theoretical and practical point of view, he believes that this therapeutic method should be tried on a large scale. It seems, in fact, that the desoxycorticosterone assumes properties similar to 17-hydroxy-11-dehydrocorticosterone (cortisone), a drug which at present is not at the disposal of the majority of the patients because of its high cost. In the discussion that followed, Professor Dogliotti confirmed, on the basis of personal experience, the good results obtainable with Lewin and Wassen's therapy in primary chronic arthritis. He expressed the opinion that success may be closely linked to a favorable quantitative relation between the doses of the two injected substances. Professor Aloisi advanced the hypothesis that the ascorbic acid acts on the desoxycorticosterone acetate by stimulating oxydation.

Electrophoresis and Chromatography in the Study of Protein

At the Superior Institute of Public Health, the Nobel prize winner Tiselius, professor of biochemistry of the University of Upsala, discussed electrophoresis and chromatography in the study of protein chemistry. He pointed out that, in the study of proteins and other substances of high molecular weight, the methods of fractioning and separation are of particular importance because they furnish fundamental indications which are necessary for chemical identification. Among the methods which have proved useful for this purpose is electrophoresis, which is based on the difference of migration of particles of substances under the influence of an electric current Progress in this field of research was recently made with special apparatus for the continuous separation of large amounts of proteins and with the use of some ultramicromethods for the analysis of a drop of serum. Another method fairly useful for studying proteins is the analysis by adsorption or chromatography, developed by Tswett in 1906 and improved by the speaker and co-workers in 1941. The solution of the protein to be studied passes through a column of suitable adsorbent. The presence of various components in the solution produces unequal concentrations, which can be observed in the filtrate as distinct zones by the use of optical methods. The diagrams thus obtained permit observation of the separation of amino acids, peptides and fatty acids, facilitating the determination of their nature and of their concentration. These studies by the speaker and his school have widened the knowledge on the mechanism of chromatography and have allowed the analysis of complex mixtures of peptides, like those which may be obtained by enzymatic digestion of various proteins.

Medicosurgical Society

The Medicosurgical Society of Pisa convened under the chairmanship of Prof. C. Cassano. Drs. Tronchetti and Torsoli reported on their study of the influence of pituitary adrenocorticotropic hormone (ACTH) on respiration and sugar metabolism in the normal person and in hyperthyroid patients. The following observations have been made after administration of the hormone: (1) a tendency to hyperglycemia on fasting, with increase of urea in the urine, (2) a low glycemic curve after oral administration of dextrose and epinephrine, (3) decreasing basal metabolic rates in hyperthyroid patients with a low respiratory rate and (4) an increase of urinary oxygenated steroids. The interpretation of these results is still dubious. Dr. Di Molfetta discussed the pathogenesis of congenital lymphangioma cysticum of the neck. From observations in two newborn infants, operated on successfully, the speaker maintains it is possible to reach a more precise understanding of the disease by taking into consideration the development of the lymphatic system. He is of the opinion that the disease starts and develops in the mesenchyma, from which the cervical lymph node develops, and that it is characterized by a modification of the formation procedure and of the evolution of this vessel-forming center.

Drs. Luciani and Merlini discussed their experience in the treatment of brucellosis melitensis with stock vaccine and autovaccine, streptomycin combined with sulfadiazine, aureomycin and chloramphenicol. They stressed in particular their results with chloramphenicol therapy. With a dose of 3 Gm. per day, they obtained defervescence in an average of five days, without toxic phenomena of importance or signs of drug intolerance. The tolerance of chloramphenicol proved to be better than that of aureomycin, while the therapeutic results were almost the same. The speakers systematically combined chloramphenicol treatment with vaccination, stressing that this can be done with safety after defervescence had been obtained with chloramphenicol. This combination of chloramphenicol and vaccine proved to be the method of choice.

Drs. Conti and Andreani reported the results of their study on lipemic variations produced by prolonged treatment with pituitary adrenocorticotropic hormone. They observed that intramuscular injection of large doses of pituitary adrenocorticotropic hormone is followed by hyperlipemic or hypolipemic reactions. The total lipids and cholesterol are constantly increased in the patients with hypopituitarism, while rapid diminution of lipemic values occurs in hyperpituitarism. In both instances a constant diminution of total lipids and cholesterol was observed after prolonged treatment with pituitary adrenocorticotropic hormone. The speakers rather exclude the possibility that the lipid and cholesterol variations induced by corticotropic stimuli should be attributed only to the metabolic modifications of the adrenal cortex, which had been stimulated to a more active production of the steroid hormones. They admit that such variations represent manifestations of the general lipid metabolism, induced and sustained by the reactivated function of the adrenal cortex. The speakers proposed the hypothesis that in the state of depressed prehypophysial function the adrenal cortex activates, but only transitorily, the mobilization of fat deposits, with limitation to the first phase of functional recovery. In every case lipopexia is stimulated by the adrenal cortex. The fat-regulating property of the adrenal cortex is also influenced by hepatic function. The patients with chronic liver disease did not manifest significant lipid variations after administration of pituitary adrenocortcotropic hormone.

year from the small sums collected at bazaars, lotteries and small festive meetings in out-of-the-way localities. In 1928, a postmaster in a small post office began to collect used postal stamps and to send the sums from their sale to the national association. Others followed his example, and now the collection and sale of such stamps has developed into a veritable industry.

During these past fruitful 40 years annual deaths from tuberculosis have declined from more than 6,000 to less than 2,000. Norway has now more than 100 tuberculosis homes with over 3,000 beds and 20 sanatoriums and coast hospitals with some 2,000 beds, with consequent negligible waiting lists. The association was subjected to unexpected stress during the German occupation of Norway. BCG vaccination, to which the association was already pledged, was to be side-tracked, according to the head of the Norwegian Public Health Service and the association was to pass over to other bodies the system of tuberculosis nursing which had already proved so effective in its hands. The board of management of the association, however, adopted an attitude of passive resistance, with the result that the continuity of its policy was assured when, in 1945, the Quisling government of Norway collapsed with the expulsion of the Germans.

The layman has much influence in the councils of the association. It is the educated layman who has contributed so largely to the education of the public. This educational factor made itself felt when, in 1947, legislation was introduced for compulsory vaccination with BCG. It received such support from popular health education that anticipated opposition did not materialize. In county after county, persons between the ages of 15 and 40 are undergoing BCG vaccination. In 1949, in the County of Østfold alone, 92 per cent of the population at the school-leaving age submitted voluntarily to this measure. It may be pointed out that the BCG legislation of 1947 was coupled with provision for the compulsory mass radiography of the community.

Clinical Studies of Malignant Hepatitis

At Medical Department B of the Rikshospital in Oslo there was an instructive collection of cases of malignant hepatitis during the years Norway was occupied by the Germans. Prof. H. A. Salvesen, who is in charge of this department, and Dr. Ola Lödöen have published an account of these cases (*Acta Med. Scandinav.* 137: 305, 1950). Their material consists of 23 cases in which the hepatitis lasted more than three months or ended fatally with the picture of acute or subacute yellow atrophy of the liver. All but three of these patients were women, and all the cases in females occurred between 1941 and 1946. During the same period there were only 14 patients (7 men and 7 women) with benign hepatitis observed in the same hospital department. Evidently patients with hepatitis in Oslo are not as a rule admitted to the hospital unless the disease is of long duration or has shown alarming symptoms.

An interesting question raised by Professor Salvesen and Dr. Lödöen concerns the etiology of malignant hepatitis. Is it, as argued by Alsted, distinct from the ordinary sporadic and epidemic hepatitis seen in peacetime, or are these two conditions merely variations in degree of one and the same disease? Salvesen and Lödöen admit the impossibility of final conclusions as long as the causative agent is unknown, ". . . but we are inclined to believe in the unity of the malignant and the usual peacetime hepatitis, chiefly because all the different types of development observed in the malignant form also have been seen in benign hepatitis, although by different observers. It is the mass action of many cases with these uncommon types of course of the disease which impresses the clinician, so that he thinks he observes a new disease."

COLOMBIA

(From a Regular Correspondent)

Bogotá, Aug. 18, 1950.

Antituberculosis Campaign

Dr. J. P. Leyva, head of the tuberculosis department of the Ministry of Hygiene, recently gave the following statistical data on the antituberculosis campaign in Colombia. There are 25 clinics in the country for the diagnosis and treatment of tuberculosis. In these clinics 67,312 intravenous injections, 134,579 intramuscular injections, 3,278 initial pneumothorax treatments and 38,261 insufflations were administered during 1949, in which year 385,120 persons had roentgen examinations of the chest. The results were positive in 4,923 persons, suspicious in 8,688 and negative in the rest. There are four tuberculosis sanitariums and a number of tuberculosis wards in general hospitals, where 7,851 bed patients were cared for and 1,323 surgical operations done in 1949. The mortality of these hospitalized patients was 1,385. In the national campaign 629,873 persons were handled during the year and the clinical laboratories and the vaccination centers made 16,540 examinations of sputum and 85,590 tuberculin tests. The fact that 150,000 tuberculous patients have not had medical aid is due to the magnitude of the problem rather than to deficiencies of the campaign.

Mosquitoes of Eastern Colombia

Dr. Julian de Zulueta of the Roberto Franco Institute of Tropical Diseases in Villavicencio has published (*Am. J. Trop. Med.* 30:325 [March] 1950) a study of the habits of mosquitoes in the savannas of Eastern Colombia. The observations were made during the rainy season, in June, July and November, 1948, and June 1949. He estimated that there were about 3,000,000 mosquitoes per square kilometer. The Anopheles, about 300,000 per square kilometer, included A. peryassui, A. pessoai, A. punctimacula and A. parvus. The commonest culicine species were Culex chrysotonum, Culex (melanoconion) sp. and Psorophora confinnis. The maximum distance between the site of capture and a breeding place was 1,800 meters. The mosquito count in the vicinity of the breeding place was approximately the same as the count 1 kilometer away. Biting activity of mosquitoes started shortly after sunset, continued during the night and increased slightly before sunrise; there was practically no biting activity during the day. Swarms of culicinae were seen over the savannas as early as 5 p. m., but mating of Anopheles was observed on only two occasions, at 7 p. m.; swarming males captured proved to be A. peryassui.

Personals

A new board of directors of the National Academy of Medicine of Colombia has been appointed for the period 1950-1952: Dr. Jose Vicente Huertas, president; Prof. Edmundo Rico, vice president; Dr. Augusto Gast Galvis, secretary, and Prof. Guillermo Uribe Cualla, treasurer.

Dr. Alfredo Luque B., professor of therapeutics and medicine, recently was appointed dean of the school of medicine of the National University of Colombia.

Dr. Alonso Carvajal Peralta, professor of the urological clinic of the school of medicine of the National University of Colombia, was recently appointed minister of hygiene.

The "Cruz Camilo Torres" was awarded by the national government to Drs. Emilo Robledo Correa and Miguel María Calle, both of Antioquia, on their completion of 50 years of professional work. These men are the first to receive this award, which was established Oct. 5, 1948.

Dr. Ernest Carrol Faust, professor of tropical diseases and hygiene, Tulane University of Louisiana, New Orleans, U. S. A., visited the school of medicine of the National University July 4-6. He delivered lectures to the school of medicine and to the Academy of Medicine of Colombia, on malaria in America and on amebiasis.

BELGIUM

(From a Regular Correspondent)

Liège, Oct. 10, 1950.

Unification of Aviation Health Measures

Belgium, France, Luxembourg, the Netherlands and the United Kingdom have agreed that, beginning Feb. 1, 1950, they will be regarded as a single territory in matters of sanitary control of air transportation. From the administrative point of view, this territory will be known among the countries of the Treaty of Brussels as the "free health zone." This new system, which is the result of efforts of the Public Health Committee of the Organization of the Treaty of Brussels, makes possible the simplification of control measures, without reducing their effectiveness. The principal points of the regulation are as follows: 1. Any airplane departing from any point of the "free health zone" will, under normal conditions, be exempted from health control measures on arrival at another point in the zone. This implies the elimination of the health declaration issued by the air command for the airplane, as well as the individual declarations on the origin and health of the passengers. 2. The health control of the crew and passengers of a plane bound for the "free health zone," coming from an airport located outside this zone, will be performed only at the first stop inside the zone. The "free health zone" can, in case of an epidemic, be restricted by the ministers of public health.

Seasonal Etiology of Retinal Detachment

Dr. Van Lint has just published in *Bruxelles-Medical* an interesting study on the influence of the seasons on detachment of the retina. He asks, "Why does the spring and summer favor detachment of the retina?" All the statistics collected so far, show that there is a seasonal factor. Three causes may contribute to it in the spring: 1. Light. 2. Movement. The active or passive movements of the whole body are frequently the cause of the detachment. The arrival of spring brings an increase of walking, running, jumping, outside activities and sports. The author cites Jeandelize, who reports detachment of the retina immediately following an energetic muscular exertion, and Vogt, who observed detachment in a myopic patient after a trip by motor car. It is also well known that movement is harmful after operation for detachment. 3. A secondary cause which deserves consideration is springtime asthenia, which appears after overwork during the winter. The author suggests, therefore, that one diminish the glaring brightness of spring with adequate glasses. Myopic persons should be advised on the health aspects of movement; they should avoid jumping, long trips, falls and, in general, any effort which causes congestion in the head.

Criminality in Belgium

At a session of the Society of Neurology and Psychiatry, Leroy, after presenting a historic survey of the economic and social development of Belgium, cites the great measures for social protection which were started under the reign of Maria Theresa (the separate system of prison discipline at Ghent). He then reported the results of the law of social protection of 1930. Criminality has diminished more than 50 per cent. Contrary to the ideas of Lombroso, the number of repeated offenses decreased simultaneously with the number of first offenses, although more slowly. This constant improvement, in spite of social depressions, is due to the rising standard of living of the masses and to the improvement in education. At present, 78 per cent of the delinquents are illiterate or poorly educated and, according to the author's experience, are mentally weak or unbalanced. Social improvement is best effected by more widespread education and better mental hygiene.

Belgian Society of Endocrinology

This society has just been organized. The number of meetings will be limited to three or four a year. The reports of the Belgian Society of Endocrinology will be published in collaboration with the French society.

NORWAY

(From a Regular Correspondent)

Oslo, Oct. 7, 1950.

Heart Disease Discovered by Mass Radiography

In the Scandinavian countries, mass radiography of whole sections of the community has hitherto usually been undertaken in a search for tuberculosis. Frequently hitherto overlooked heart disease is discovered. In Stavanger, the fourth largest town in Norway, Johan Riis has lately shown that among 36,000 persons over the age of 14 examined in this way, there were as many as 290 with signs of heart disease. On closer examination of 286 of these persons, 268 were found to have heart disease; this diagnosis could not be confirmed in the remaining 18. Among the 290 were 179 over the age of 60. There were 88 with valvular disease of the heart, usually rheumatic, and 163 with high blood pressure as well as heart lesions. About one third of all these persons (92) were already aware of their heart disease. About one fifth were in need of immediate treatment.

In Stockholm, Westman found radiologic signs of heart disease in 328 persons under the age of 60 out of a total of 63,877 persons undergoing mass radiography. Among these 328 persons were 111 with acquired valvular disease of the heart, usually rheumatic. There were 59 with high blood pressure combined with cardiac lesions and 53 with congenital heart disease. About one third were unaware of their heart disease, though most of them had experienced symptoms suggestive of it. In many cases there had indeed been pronounced symptoms, but a physician had not been consulted for fear he would confirm suspicions.

Commenting on this state of affairs, Dr. O. Jervell of Oslo draws attention to confirmatory observations elsewhere, including the United States. He quotes White as estimating that about 2 per cent of the inhabitants of Northern United States suffer from heart disease. With mass radiography revealing heart disease in about 1 per cent of all the persons examined, it would seem that about every other case of heart disease would be incidentally discovered. Dr. Jervell is not quite sure this is an important advance, for he does not have blind confidence in wholesale radiologic diagnoses; even the electrocardiographic signs of heart disease are not, in his opinion, always a true index of real heart disease. "Whatever the methods we employ for the mass examination of healthy persons, we must not attach too much importance to findings differing from the normal."

National Antituberculosis Association

This summer the Norwegian National Antituberculosis Association celebrated its fortieth anniversary in Bergen. The association's president, Dr. Harold Bjelke, took this opportunity to trace its history and review its achievements. The Norwegian Medical Association was originally responsible for the foundation of this national organization in the fight against tuberculosis, and at first its direction was almost entirely in the hands of doctors. Bit by bit laymen have come to take a more active part, and at present the policy of the association reflects the layman's as well as the doctor's point of view. Since its modest beginning in 1910, the association has learned to handle seven-figure budgets which would have staggered its founders. Apart from the millions received as a voluntary organization, there are the substantial contributions made to the association by the state. Yet the greatest source of revenue has come year by year from the small sums collected at bazaars, lotteries and small festive meetings in out-of-the-way localities. In 1928, a postmaster in a small post office began to collect used postal stamps and to send the sums from their sale to the national association. Others followed his example, and now the collection and sale of such stamps has developed into a veritable industry.

During these past fruitful 40 years annual deaths from tuberculosis have declined from more than 6,000 to less than 2,000. Norway has now more than 100 tuberculosis homes with over 3,000 beds and 20 sanatoriums and coast hospitals with some 2,000 beds, with consequent negligible waiting lists. The association was subjected to unexpected stress during the German occupation of Norway. BCG vaccination, to which the association was already pledged, was to be side-tracked, according to the head of the Norwegian Public Health Service and the association was to pass over to other bodies the system of tuberculosis nursing which had already proved so effective in its hands. The board of management of the association, however, adopted an attitude of passive resistance, with the result that the continuity of its policy was assured when, in 1945, the Quisling government of Norway collapsed with the expulsion of the Germans.

The layman has much influence in the councils of the association. It is the educated layman who has contributed so largely to the education of the public. This educational factor made itself felt when, in 1947, legislation was introduced for compulsory vaccination with BCG. It received such support from popular health education that anticipated opposition did not materialize. In county after county, persons between the ages of 15 and 40 are undergoing BCG vaccination. In 1949, in the County of Østfold alone, 92 per cent of the population at the school-leaving age submitted voluntarily to this measure. It may be pointed out that the BCG legislation of 1947 was coupled with provision for the compulsory mass radiography of the community.

Clinical Studies of Malignant Hepatitis

At Medical Department B of the Rikshospital in Oslo there was an instructive collection of cases of malignant hepatitis during the years Norway was occupied by the Germans. Prof. H. A. Salvesen, who is in charge of this department, and Dr. Ola Lödöen have published an account of these cases (*Acta Med. Scandinav.* 137: 305, 1950). Their material consists of 23 cases in which the hepatitis lasted more than three months or ended fatally with the picture of acute or subacute yellow atrophy of the liver. All but three of these patients were women, and all the cases in females occurred between 1941 and 1946. During the same period there were only 14 patients (7 men and 7 women) with benign hepatitis observed in the same hospital department. Evidently patients with hepatitis in Oslo are not as a rule admitted to the hospital unless the disease is of long duration or has shown alarming symptoms.

An interesting question raised by Professor Salvesen and Dr. Lödöen concerns the etiology of malignant hepatitis. Is it, as argued by Alsted, distinct from the ordinary sporadic and epidemic hepatitis seen in peacetime, or are these two conditions merely variations in degree of one and the same disease? Salvesen and Lödöen admit the impossibility of final conclusions as long as the causative agent is unknown, ". . . but we are inclined to believe in the unity of the malignant and the usual peacetime hepatitis, chiefly because all the different types of development observed in the malignant form also have been seen in benign hepatitis, although by different observers. It is the mass action of many cases with these uncommon types of course of the disease which impresses the clinician, so that he thinks he observes a new disease."

COLOMBIA

(From a Regular Correspondent)

BOGOTÁ, Aug. 18, 1950.

Antituberculosis Campaign

Dr. J. P. Leyva, head of the tuberculosis department of the Ministry of Hygiene, recently gave the following statistical data on the antituberculosis campaign in Colombia. There are 25 clinics in the country for the diagnosis and treatment of tuberculosis. In these clinics 67,312 intravenous injections, 134,579 intramuscular injections, 3,278 initial pneumothorax treatments and 38,261 insufflations were administered during 1949, in which year 385,120 persons had roentgen examinations of the chest. The results were positive in 4,923 persons, suspicious in 8,688 and negative in the rest. There are four tuberculosis sanitariums and a number of tuberculosis wards in general hospitals, where 7,851 bed patients were cared for and 1,323 surgical operations done in 1949. The mortality of these hospitalized patients was 1,385. In the national campaign 629,873 persons were handled during the year and the clinical laboratories and the vaccination centers made 16,540 examinations of sputum and 85,590 tuberculin tests. The fact that 150,000 tuberculous patients have not had medical aid is due to the magnitude of the problem rather than to deficiencies of the campaign.

Mosquitoes of Eastern Colombia

Dr. Julian de Zulueta of the Roberto Franco Institute of Tropical Diseases in Villavicencio has published (*Am. J. Trop. Med.* 30:325 [March] 1950) a study of the habits of mosquitoes in the savannas of Eastern Colombia. The observations were made during the rainy season, in June, July and November, 1948, and June 1949. He estimated that there were about 3,000,000 *mosquitoes per square kilometer.* The *Anopheles,* about 300,000 per square kilometer, included A. peryassui, A. pessoai, A. punctimacula and A. parvus. The commonest culicine species were Culex chrysotonum, Culex (melanoconion) sp. and Psorophora confinnis. The maximum distance between the site of capture and a breeding place was 1,800 meters. The mosquito count in the vicinity of the breeding place was approximately the same as the count 1 kilometer away. Biting activity of mosquitoes started shortly after sunset, continued during the night and increased slightly before sunrise; there was practically no biting activity during the day. Swarms of culicinae were seen over the savannas as early as 5 p. m., but mating of Anopheles was observed on only two occasions, at 7 p. m.; swarming males captured proved to be A. peryassui.

Personals

A new board of directors of the National Academy of Medicine of Colombia has been appointed for the period 1950-1952: Dr. Jose Vicente Huertas, president; Prof. Edmundo Rico, vice president; Dr. Augusto Gast Galvis, secretary, and Prof. Guillermo Uribe Cualla, treasurer.

Dr. Alfredo Luque B., professor of therapeutics and medicine, recently was appointed dean of the school of medicine of the National University of Colombia.

Dr. Alonso Carvajal Peralta, professor of the urological clinic of the school of medicine of the National University of Colombia, was recently appointed minister of hygiene.

The "Cruz Camilo Torres" was awarded by the national government to Drs. Emilo Robledo Correa and Miguel María Calle, both of Antioquia, on their completion of 50 years of professional work. These men are the first to receive this award, which was established Oct. 5, 1948.

Dr. Ernest Carrol Faust, professor of tropical diseases and hygiene, Tulane University of Louisiana, New Orleans, U. S. A., visited the school of medicine of the National University July 4-6. He delivered lectures to the school of medicine and to the Academy of Medicine of Colombia, on malaria in America and on amebiasis.

CORRESPONDENCE

CANCER OF THE BREAST AND ESTROGENIC THERAPY

To the Editor:—In the article "Cancer of the Breast: Classification of Cases, Criteria of Incurability and Treatment," by U. V. Portmann (*J. A. M. A.* 144:513 [Oct. 14] 1950), there are two statements which may need amendment or correction.

On page 516, first column, the next to last paragraph starts: "Although it has been proved that administration of estrogens may induce cancer of the breast and stimulate growth. . . ." Any thorough review of the subject will reveal the fact that cancer of the breast has been induced by estrogens only in especially sensitive strains of rats that were inbred in order to have a highly hereditary tendency to breast cancer. These results were obtained only with massive doses of estrogens which are in no way comparable to the doses used in human application. Nobody disagrees with the theory that estrogens probably stimulate growth of preexisting breast cancer, but the unqualified statement quoted from Dr. Portmann's paper may lead to considerable confusion and should, I believe, be properly amended.

In the last two lines of the same column the author says, "My associates and I give testosterone propionate in doses of 50 to 100 mg. intravenously three times a week." As testosterone propionate is not soluble in water, but only in oil and similar solvents, and rather poorly at that, I am afraid that 1 or 2 cc. of oil administered intravenously, just once, will not allow much further continuation of therapy. Undoubtedly the author meant to say "intramuscularly" and the error was missed in the proofreading. (A correction was published in The Journal Oct. 21, page 701.—Ed.)

IRRITANT ACTION OF IODOACETIC ACID

To the Editor:—Two cases of bullous dermatitis due to contact with iodoacetic acid were reported in The Journal of March 18 (page 805). It has been suggested that the chemical acted as a primary irritant, although the possibility of a sensitization mechanism has not been ruled out in these two cases. In the past we had opportunity to carry out experiments which established the fact that iodoacetic acid acts as a primary irritant. A biochemist noted the appearance of small blisters on his hands and traced them to contact with minute crystals of iodoacetate, commonly used as an enzyme inhibitor in biochemical studies. Control experiments with iodoacetate patch tests in nonexposed subjects revealed that even a 10 minute contact was sufficient to cause a painful bullous lesion at the site of application, followed by superficial epidermal necrosis and scarring in all subjects tested.

From the studies of Peters and co-workers on the biochemistry of skin in "Modern Trends in Dermatology" (edited by R. M. B. McKenna, London, Harper & Brothers, 1948) and of Dixon and Needham (*Nature* 158:432, 1946) the mode of action of iodoacetate may be explained as follows: A large variety of sulfhydryl inhibitors, such as lewisite, mustard, methyl bromide and nitrogen mustard, cause blister formation most probably through inactivation of the free sulfhydryl groups of certain essential glycolytic enzymes (hexokinase, pyruvate oxidase). It may be assumed that iodoacetate, one of the most potent sulfhydryl inhibitors, acts by a similar mechanism. This view is supported by the histochemical observation that the sulfhydryl groups of the epidermis are inactivated by iodoacetamide (Goffart, M.: Interaction of Vesicants, Oxidizing Agents and Metal Ions with the Sulfhydryl Groups in the Skin (*Arch. internat. de pharmacodyn. et de thérap.* 74:9, 1947).

REQUESTS FOR REPRINTS

To the Editor:—Physicians, those interested in investigative work in particular, have devised a penny postcard system by which they save themselves time and money in securing reprints of articles. It would be no more difficult for these efficient penny postcards to be written so that the name and address of the person requesting the reprint appear on the lower portion of the card so that this section of the card could be detached and pasted on the envelope in which the reprint is sent. This would not only save time for the author who does not have a secretary but would facilitate the delivery of the reprint because the correct name and address would be on the envelope. The author should use a good grade of glue when affixing the detached section of the card onto the envelope.

INSPECTION OF HOSPITALS

To the Editor:—I have been instructed to send you a copy of a resolution passed by the Kalamazoo Academy of Medicine at their last regular meeting, Oct. 17, 1950. The resolution is as follows: "The Kalamazoo Academy of Medicine heartily endorses the editorial in The Journal of the American Medical Association of Sept. 30, 1950, on "Inspection of Hospitals by Hospitals" and that a copy of this resolution be sent to the superintendent of Bronson Methodist Hospital, Kalamazoo, Mich.; the Board of Trustees, Bronson Methodist Hospital, Kalamazoo; Superintendent of Borgess Hospital, Kalamazoo; Michigan Hospital Association; the Secretary of the Michigan State Medical Society, and the Editor of The Journal of the American Medical Association.

Council on Medical Education and Hospitals

The following statement was adopted on Nov. 1, 1950 by the Joint Committee on Medical Education in Time of National Emergency representing the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges. This statement has been submitted to the National Advisory Committee on the Selection of Doctors, Dentists and Allied Specialists to the Selective Service System and the Health Resources Advisory Committee to the National Security Resources Board.

DONALD G. ANDERSON, M.D., *Secretary.*

MEDICAL EDUCATION IN TIME OF NATIONAL EMERGENCY

The mounting tension of the times confronts medical education with great responsibilities. Only physicians trained as highly as the state of medical knowledge and available resources will permit can serve the national interest well, whether this be in a military or in a civilian capacity. In full recognition of the need of both the armed forces and the civilian population for good medical care, as many well trained physicians as possible should be produced. To accomplish this aim in time of emergency, the following proposals are offered by *The Joint Committee on Medical Education in Time of National Emergency,* which represents the Executive Council of the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association. These proposals have been formulated in order to profit from the experiences of World War II, to avoid a repetition of the mistakes made then and to attempt to prevent the occurrence of new errors.

The duration of the emergency on which we have entered, and of the policy of limited mobilization are at this time quite unknown. The longer or more serious the emergency, the greater will be the demand for physicians—for well trained physicians. One of the hard lessons learned from the medical training program employed in World War II was that in the national interest demands for speed and quantity should never be permitted to interfere with quality.

It is, consequently, especially important that no steps be taken at the beginning of the present emergency that will interfere with the adequate training of physicians, either as medical students or as interns and residents, or with the supply of properly trained basic scientists. If, as now appears probable, the emergency bids fair to be prolonged over many years, we must exercise great care that, in instituting measures necessary to meet the pressing and immediate demands of the emergency, we do not interfere with the continuous training of physicians. Such training requires an uninterrupted supply of students through college into and through medical school and hospitals; it requires a smaller but vitally important supply of graduate students in the basic and clinical sciences; and, it requires, also, the maintenance of an adequate basic science, as well as clinical faculty. It requires continuation of the principles of individual student participation and instruction which are basic to good medical education and which would be vitiated by acceleration, overcrowding of students or loss of faculty to the point where attention to the individual student would be diminished.

At a time when the armed forces and the civilian population both at home and abroad are demanding doctors, it is the responsibility of the medical schools to outline the conditions necessary in a critical period to the adequate training of doctors so that they will best be able to serve society. These proposals attempt to outline these conditions as they apply in a time of national emergency.

Depending on the degree of emergency, three possible methods of organization of our society might be instituted:

1. Partial Mobilization
    a. Limited mobilization (as in effect now)
    b. Extensive mobilization (as in World War II)
2. Total Mobilization (as under a National Service Act)

The primary emphasis in the proposals which follow is on policies and procedures in periods of *Partial*—and not of *Total*—mobilization. Should total mobilization be adopted as a national policy, students, faculty and physicians would then be assigned to civilian or military duty or to study, teaching or research. This would probably remove the stigma from those not in military service and not wearing a uniform. It is, however, our earnest hope that adequate mobilization of national resources and manpower can be achieved without the necessity of recourse to total controls. The proposals herewith submitted are, however, adaptable to a program of total mobilization, should this be imposed.

Whether or not the country is engaged in waging war, it is probable that a state of national emergency will be long lasting. Since well trained physicians will continue to be required, the provisions necessary to guarantee the quality of their training will apply to the problems of recovery and reconstruction following cessation of military activities, quite as much as they do in a time of immediate emergency. Problems relating to transition from a time of emergency to a state of peace will be studied by the Joint Committee when some picture of the conditions likely to be prevailing at that time becomes visible. The medical profession and the medical schools stand ready to make all adjustments needed to meet the emergency. Medical schools, hospitals and other civilian institutions should study carefully the problem of utilizing personnel with maximum efficiency in the discharge of their responsibilities to the nation and should be prepared, whenever necessary to redefine in the light of these studies, their needs for medical manpower. The governmental services should likewise continually reexamine their utilization of medical manpower to the end that an expanded military establishment will not impair the health of the nation by unnecessarily disrupting the training of physicians or widely or irregularly withdrawing doctors from the care of the civilian population.

Since physicians trained by the medical schools, universities and hospitals are as essential to the government as are the graduates from the military service schools, it is encumbent upon the Federal government to guard the integrity of medical education in time of emergency, as in time of peace. The need for hasty mobilization occasioned by the Korean war has led to irregularly extensive withdrawals of professional personnel, a process which should be controlled now by the immediate utilization of central and local committees empowered to adjudicate national and local questions of availability and essentiality of medical manpower.

Proposals

1. *Deferment of Preprofessional College Students.*—A procedure for deferment of preprofessional college students in the field of medicine, dentistry, veterinary medicine and osteopathy is provided by Selective Service Local Board Memorandum No. 7. A broader plan for deferment of college students in all fields of study has been recommended to General Hershey by the five Scientific Advisory Committees to the Selective Service System and by the Healing Arts Educational Advisory Committee of the Selective Service System and has been approved by him in principle but is still under study and has not been adopted as official policy. This plan is based upon (*a*) the standing of students in the freshman and subsequent years of college and (*b*) a scholastic aptitude test. This test should be administered by a nationally recognized testing service, such as the Educational Testing Service of Princeton, N. J. This broader plan is enthusiastically endorsed by the Joint Committee. The Committee urges prompt adoption and implementation of this plan. The Joint Committee is not favorable to the policy of identification and selection by medical schools of college students as "premedical students" early in their college careers, which appears to be implied in the following sentence in the new law for induction of medical, dental and allied specialists:

"It is the sense of the Congress that the President shall provide for the annual deferment from training and service under this title of numbers of optometry students and premedical, preosteopathic, preveterinary, preoptometry and predental students at least equal to the numbers of male optometry, premedical, preosteopathic, preveterinary, preoptometry and predental students in attendance at colleges and universities in the United States at the present levels, as determined by the Director."

The Joint Committee recommends that students desiring to study medicine be included in the broad deferment plan for college students mentioned above.

2. *Duration of College Training.*—So long as the national circumstances permit the basic structure of collegiate education to continue undisturbed, four years of college training prior to entrance into medical school is desirable. In an emergency requiring extensive mobilization, the period of college training prior to entrance into medical school could be reduced to ninety semester hours, contained in three academic years of college training. This would involve 90-110 weeks of actual study.

The curriculum for those planning to enter medicine should be kept flexible during the college period. The emphasis should be on developing the students' capacities and attitudes quite as well as on instilling specific scientific knowledge. The student must continue to demonstrate superior performance in the courses that are regularly required for admission to medical school.

3. *Selection of Medical Students.*—The selection of all medical students, and, we believe, of all professional students, should be in the hands of the individual professional schools, for only in this way is it possible to secure the best candidates for medical study. The period for accepting applications and commencing and concluding the acceptance of medical students should be as uniform as possible.

Qualified individuals on active duty who secure permission from the Armed Forces, Public Health Service or Veterans Administration to apply for admission to medical school should be eligible for consideration with other candidates for admission. If accepted for admission, we believe that such students should be placed on inactive duty during the period of medical training, including undergraduate and graduate phases. During this training, they could wear special identifying insignia.

A satisfactory mechanism for the deferment of medical students who are registrants with the Selective Service System is provided at present by Local Board Memorandum No. 7.

On the basis of experience with the AST and V-12 programs in World War II, we believe very strongly that it is neither desirable to place medical students in uniform nor to have them subsidized as a group by the government. It might be wise to have a special insignia which could be worn by the students to indicate that they have been deferred, or, if commissioned, placed on an inactive duty status, for study considered essential to the health and welfare of the nation.

In place of such induction and full payment of medical students as was conducted under the AST and V-12 programs in World War II, we believe consideration should be given to the inauguration of a system of governmental scholarships which would be available to students on the basis of economic need or as a reward for academic superiority. A program providing government loans should also be considered. The medical schools should be charged with the responsibility of selecting the recipients of these scholarships or loans.

Medical schools should, of course, continue to accept properly qualified female students and properly qualified male students who may be physically unacceptable to the armed services.

4. *Obligation of Medical Students to Serve Their Country Following Graduation.*—The status of students and their obligation to serve will, it is recognized, depend on national circumstances. A plan should be devised which will define clearly the obligation of students who have been deferred for professional study to serve the government subsequent to completion of their training. *Deferment* should not indicate exemption from government service, but merely *delay or postponement* of service. Students deferred by the Selective Service System should on completion of hospital or other graduate training and on certification of availability by such appropriate agencies as the National Advisory Committee on the Selection of Doctors, Dentists, and Allied Specialists to the Selective Service System and the Health Resources Advisory Committee to the National Security Resources Board be obligated over a period of years to serve when needed in such federal services as the Armed Forces, Public Health Service or Veterans Administration hospital program for a period consistent with the obligation of others for military service. The certification of availability referred to above should be made after consideration of the civilian, public health and welfare needs, including essential research and teaching. Deferment, therefore, has as its only objective a later service in a needed capacity.

As this problem is being studied by appropriate government agencies, representatives of the medical schools and the medical profession should participate in the formulation of policies.

5. *The Medical School Curriculum.*—The continuous 36 month accelerated program in the medical schools during World War II was almost universally recognized as a major cause of production of poorly trained doctors. It was exhausting to students and faculty alike and developed immature physicians. Such a program of acceleration could not be reinstated in the present emergency without very serious disruption of the training of physicians, not only for the reasons stated above, but also because at least one-third of the medical schools have now extended one or more of their academic years from 9 months to 10, 11 or 12 months. This is because the extension of knowledge has made it appropriate for some schools to increase the length of their basic science years and because many schools have found it necessary to utilize an 11 or 12 month third or fourth year, or both, in order to provide adequate training in public health, psychiatry and other newly emphasized disciplines. Indeed only by using their clinical facilities over this extended period have a number of schools found it possible to provide an adequate training in medicine and surgery and other clinical subjects.

For the majority of medical schools the committee recommends as an essential during an extensive emergency or war that the curriculum extend over four 12 month years. This would permit continuation of the program already under way in many schools. It would also provide opportunity for inclusion during extended academic years or special periods of new material essential for national welfare and security, especially in time of emergency. Studies of atomic energy, radiation sickness and protection, blast injury, bacteriological and chemical warfare, the handling of mass casualities and other aspects of civilian defense, special problems in epidemiology, industrial medicine and hygiene, rehabilitation and utilization of manpower, military medicine, tropical medicine and needed military procedures would be included. Consideration by the Joint Committee of the content of such studies is under way in consultation with representatives of the Surgeon General of the Public Health Service, the Director of Medical Services, office of the Secretary of Defense, the Surgeons General of each of the Armed Forces, the Chief Medical Director of the Veterans Administration, the Director of the Health Resources office of the National Security Resources Board, the Medical Schools and the Medical Film Institute. It is already clear that some of the material can be integrated into the existing curriculum; it is equally clear that new time, new courses, new teachers must be found if medical students are to be trained adequately in these important areas.

During a period of extensive mobilization, it is probable that students will not be deferred during long summer vacations. If the college year ends in June, medical schools operating under the proposed four 12 month year curriculum might, therefore, be expected to begin in July. Students would then graduate from medical school in June at the end of four 12 month years. As long, however, as vacation is permitted after completion of college, and medical schools continue to commence in September, three 12 month and one 9 month year are recommended. The few schools which elect to operate on an accelerated program should, of course, be free to continue to do so. In any of these programs, summer vacation periods, normally three months in length, could be limited to one month at the end of the freshman year and either one month or two weeks at the end of the second and third years, the remaining two weeks being inserted at the end of quarters or semesters during the school year.

Many schools would doubtless wish to incorporate much of the new material into their regular courses or clerkships, extended in length. Others might wish to devote two month periods either in the summer or between quarters or semesters to special study given either by their own faculty or perhaps by representatives of governmental agencies. During such periods in schools where R.O.T.C. programs are in effect, students could be sent to a camp or a clerkship in a military hospital. In such periods some groups might be sent to special centers or schools for instruction in atomic medicine or civilian defense. Some schools operating on an accelerated program might wish to place such special instruction at the end of the established academic program. The final program should be that which in the judgment of each school is most consistent with its program of maintenance of high standards of medical education and the promotion of the public welfare. At the end of such a four year program, graduating physicians would be more mature, better trained in their profession and also have basic training in matters of public health, civilian defense and military medicine. When, in addition, they complete their hospital and graduate training, they should be prepared for duty necessary to the national health, safety and welfare without the necessity of preliminary orientation, even after entrance into active military duty.

6. *Number of Students in Medical School.*—Since the end of World War II the medical schools, by expanding their facilities and faculties, have been able to increase the number of students admitted annually from a prewar average of 6000 to over 7000. It is recognized that in an emergency of any duration a further increase in production of physicians will be necessary. Since most medical schools are today maximally expanded and some even over-expanded, it is clear that, in order to produce more physicians, they will need more faculties and facilities. To accomplish this would require additional funds and additional teachers. It is clearly the obligation of each school to explore anew its resources with a view to determining, if possible, how and to what extent it can increase its output without lowering quality and what it will require to do so.

It should be obvious that the depletion of existing faculty through service in the Armed Forces of significant numbers of active teachers, including graduate students and hospital residents, such as occurred in World War II, would not only reduce the quality of present teaching but would work in direct opposition to any program for increasing the supply of physicians. Such depletion might, indeed, necessitate a reduction in enrolment in medical schools.

7. *Faculty Requirements.*—The maintenance of adequate faculties is essential if medical schools in a national emergency are to meet the demands placed on them for the education of medical students, the advanced training of physicians, basic scientists, investigators, and new teachers; for the prosecution of research important to the national health, safety and welfare; and for the training of ancillary personnel in the health services.

To maintain the faculties of medical schools at proper strength for the accomplishment of these objectives, it is imperative that there be established without delay an effective, coordinated and enlightened program regulating the entrance into military duty, both on a voluntary and on an involuntary basis, of those who constitute the faculties of the medical schools. This program should be so designed that the stigma of evasion will not be attached to those deferred for essential activities related to medical education. It is urged that the National Advisory Committee on the Selection of Doctors, Dentists and Allied Specialists to the Selective Service System and the Health Resources Advisory Committee to the National Security Resources Board formulate without delay, for the guidance of local advisory committees, principles and policies governing this important phase of the selection and distribution of physicians between the civilian population and the armed services.

The actual selection of individuals at all levels, in conformity with these principles and policies, should reside in local communities, organizations and institutions, so far as education is concerned in medical schools and teaching hospitals. It is strongly urged that the local committees in areas in which medical schools are located include the deans of such schools or their representatives. The educational institutions, with which this statement is particularly concerned, should be directed to assess and report not only their minimum needs for continuing operation, but also their capacity to expand and the requirements for such expansion without deterioration of quality of education.

The minimum faculty essential for the conduct of a satisfactory program of medical education must be carefully safeguarded and maintained. This minimum will vary from medical school to medical school and will depend on many factors such as the size of the school and its other responsibilities for research, for medical service and for the teaching of groups other than undergraduate medical students, e. g. graduate students, practicing physicians and students in other colleges of the university of which the medical school is a part.

This minimum number of essential teachers obviously must be related to the size of the normal peacetime faculty of the medical school; e. g., some medical schools can release very few faculty members without seriously handicapping their teaching program, while other medical schools, particularly those with relatively larger faculties, can release more without deterioration in the quality of their instructional programs. On the other hand certain schools ought to add faculty members.

Local and state advisory committees to the Selective Service System should be required to discover the needs of the individual medical schools for faculty members both for undergraduate medical student instruction and for the other essential activities carried out by the medical schools and to make adequate allowance for these needs.

In time of limited or extensive mobilization the problem of faculty morale is a difficult one. Essential teachers who are liable for military service must either be deferred or inducted and assigned on inactive duty to the medical school. There are, however, those among the faculty who are unwilling to be declared essential. Some of these might be appointed consultants to military hospitals in the vicinity so that they may be of service from time to time on a temporary duty status. Some may be allowed to enter service. For these, however, the period of active duty should be for a clearly limited period of time, such as two years, after which they should be returned to the faculty. In their military assignment consideration should be given to their technical knowledge and skills and their ability to teach. In their place on the faculty, substitutes or exchanges might be released from active service. Such exchanges should be equivalent both as to function and competence. Such a rotation of faculty members while, of course, easier to implement in the clinical than in the basic science fields, and while presenting some problems in the development of sustained and continuing programs of instruction, would be preferable to the loss of key faculty members for tours of duty lasting four, five or more years. Perhaps a similar scheme of rotation between civilian and military duty could be extended to many practicing physicians.

Such arrangements for rotation would seem to offer great advantages in terms of (1) supply, (2) morale, (3) professional ability of medical officers and faculty alike. If faculty members on active duty had the opportunity to return to the medical schools for teaching, study and research, their incentive and skill would be increased. Likewise, their presence in the schools would be of great value in the training of students in the meaning and the value of military training.

The maintenance of a continuous supply of new faculty members is as great a need as is the continuous supply of premedical and medical students. This is true both for basic science and clinical faculty.

8. *Graduate Students in the Basic Medical Sciences.*—To maintain the flow of basic science faculty, graduate students in the basic sciences, both in college and medical school must be deferred for study, teaching and research. The failure to do this in World War II produced a severe shortage in supply of basic

science preclinical faculty, a shortage from which we will suffer and which would be seriously exaggerated if a more intelligent policy were not put into effect in the present emergency.

It is imperative that this need be kept in mind by the National Advisory Committee on the Selection of Doctors, Dentists and Allied Specialists to the Selective Service System and the Health Resources Advisory Committee to the National Security Resources Board, and by local advisory committees. It may be easier for local committees to understand the community needs for medical practitioners and even for hospital residents than for graduate and postgraduate students and basic science faculty. It is, therefore, essential that clear instructions be issued so that the significant part that men in these areas play in the production of qualified physicians is fairly evaluated and clearly understood.

9. *Interns.*—All internships should be at least 12 months in length. When feasible in light of the needs, some longer internships should be permitted. The nine month internships during World War II were universally recognized as unsatisfactory. All medical school graduates should be permitted an internship or equivalent training as graduate or postgraduate students. Interns and graduate students should be selected by the hospitals and medical schools as in peacetime.

10. *Residents.*—Residency training is a form of postgraduate education without which it is impossible to produce a continuing flow of competent teachers, clinical investigators and specialists. These residents are essential to adequate patient care in the better hospitals. Furthermore these residents constitute one of the largest and most helpful group of teachers and research workers.

It is recognized that a national emergency with its immediate demands for men will result in some limitation of residency training. It cannot be too strongly emphasized, however, that no matter how serious the emergency may become, there will always be urgent need for a program that provides for the continuous training of residents.

During World War II a percentage of residents were deferred for 9-18 months of residency. Because, however, residents completing even a full "9-9-9" experience were insufficiently trained to justify the temporary loss in medical manpower entailed in their residency training, the nine months' residency in World War II was unsatisfactory. The saving in time under the "9-9-9" program proved to be false economy.

It is now recognized that internship and residency training are as integral parts of the training of a physician as is his undergraduate medical course. Consequently a policy of indiscriminant issuance of commissions to residents who volunteer for service (under Public Law 779), without possibility of deferment to meet essential situations, would be shortsighted. Its general application might mean that, for all practical purposes, next year there would be no residents. Even if a policy of return of officers from active duty to undertake residency training is undertaken, it may be two or three years before such officers are returned. There will be a serious break in the chain of residency training. This will interrupt the training of specialists important alike to the Armed Forces and to the civilian population and will disrupt the clinical clerkship teaching of medical students.

It is recognized that opportunities for residency training should be available to properly qualified individuals who have been in active service; and that following one or two years of hospital training after graduation from medical school, many young physicians could be expected to serve on active military duty for a suitable period before returning to undertake or to complete residency training. This program should not, however, be permitted to interfere with a policy of deferment of selected junior as well as senior residents for proper training in teaching hospitals. This policy should become the immediate responsibility of the National Advisory Committee on the Selection of Doctors, Dentists and Allied Specialists to the Selective Service System and the Health Resources Advisory Committee to the National Security Resources Board who should so advise each local advisory committee so that the presently threatened disruption of the residency training program can be brought under control.

11. *Medical Education Under Universal Military Training or a National Service Act Involving Total Mobilization.*—No extensive discussion is attempted here of the effect of a Universal Military Training Program or of a National Service Act upon medical education. It is felt such a discussion should be deferred until more specific information is available concerning such programs or the possibility of their development. It must be clear, however, that even under U.M.T. or a National Service Act adequate provision must be made for a continuing flow of premedical and other science students, medical students, interns, residents and graduate students in the basic sciences and for retention of adequate faculty to supply the necessary training. The proposals which have been submitted in this report are, it is believed, readily adaptable to conditions of full mobilization under a National Service Act.

In any universal military training program which might be adopted, provision should be made for a delay in the period of required service of qualified preprofessional college students until they have completed their college and professional training or have discontinued the program. This plan should employ the principles recommended earlier in this document for the deferment of outstanding college students under the present Selective Service Act. Such students would thus be able to serve society and their government later in their special needed capacity. They should not be called upon to perform double duty for the Armed Forces.

Summary

1. To insure the continued production of well qualified medical graduates, provision must be made for an adequate supply of premedical students.

2. The duration of premedical study should not be reduced below 90 semester hours, the equivalent of 3 academic years.

3. All medical students should be selected by the medical schools.

4. Subsequent to graduation and internship, deferred medical students should, if certified as available by such appropriate agencies as the National Advisory Committee on the Selection of Doctors, Dentists and Allied Specialists to the Selective Service System and the Health Resources Advisory Committee to the National Security Resources Board, be obligated to serve when needed in the Armed Forces or other specified government services.

5. The curriculum of medical study should be reorganized to give proper emphasis to subjects of particular importance for the national health, security and welfare in time of national emergency.

6. Medical schools should exert every effort to admit as many medical students as they can train without deterioration of the quality of medical training they can provide. Provision should be made for the increased financial support essential to the provision and maintenance of the increase in faculty, facilities and buildings required to accomplish the proposed increase in enrolments.

7. The maintenance and replenishment of adequate faculties in the medical schools are absolutely essential to the continuing production of well trained physicians to meet the needs of the civilian population and Armed Forces.

8. All medical school graduates should have an internship or graduate or postgraduate training of 12 or more months' duration.

9. The continuation of an active residency training program is essential to adequate professional training, teaching and medical care, even in the gravest emergency.

10. Provision for training of young men in the basic medical sciences, including graduate training, is also essential for the teaching and research functions of the medical schools and for the prosecution of research programs elsewhere. Properly qualified personnel, whether they do or do not hold a degree in medicine, should be deferred or assigned to these activities rather than to active military duty.

Conclusion

In time of emergency, just as in time of peace, an important phase of national security—the maintenance of health—demands highly trained physicians in sufficient numbers. The objective of the present proposals is the maintenance of this supply of physicians. These proposals reflect the critical and intensive thinking of medical educators who since World War II have been studying this problem so as to benefit from the experience and mistakes of World War II. They have been developed after full opportunity to obtain the suggestions of representatives of the governmental agencies concerned. These experiences, and consequently these proposals, emphasize the fundamental truth that in medicine there can be no substitute for adequate training. It is urged, therefore, that in the best interest of the nation this principle be recognized fully in all plans for medical education that may be adopted in the present or future emergencies.

Medical Motion Pictures

Subcutaneous Blood Flow in the Bat. Reel I, Vascular Patterns. Reel II, Behavior of Blood and Vascular Components. Reel III, Active Vasomotion. 16 mm., black and white, sound, showing time 30 minutes. Prepared by Richard L. Webb, Ph.D., Department of Anatomy, and Paul A. Nicoll, Ph.D., Department of Physiology, Indiana University, Bloomington. Supported in part through a research contract with the Air Material Command, Wright Field, Dayton, Ohio. Produced in 1948 by and procurable on rental or purchase from Audio-Visual Center, Indiana University, Bloomington, Ind.

These films were designed to show peripheral circulation and the nature and behavior of minute blood vessels in their normal environment. By spontaneous and induced vasoconstriction, this motion picture portrays the slow motion in blood vessels of a mammalian species. The red blood cells appear as biconcave disks, which is a distinct improvement over previous vascular pictures of the mesentery of the frog, where oval nucleated cells are seen. Vasomotion in arterioles by contraction of vitally dyed spiral smooth muscles, rhythmic contractions of the vein, functions of the valves in the veins, action of precapillary sphincters and differentiation of endothelial cells, leukocytes and thrombocytes are all well visualized. The thrombocyte and leukocyte reaction to injury is also adequately portrayed.

While these films show superb photomicrographic technic, the ideal motion picture on this subject should have interspersed short sections of animated drawings to allow the student to visualize the events taking place. The only photographic fault appears as the camera moves, when one notes a matrix of cellular debris which is apparently adherent to the lens system. This production should be excellent for showing to physiology and biologic science students.

Each of the three reels deals with a definite phase of circulation in its respective title and may be used separately and repeatedly for intensive studies of its special province. It is suggested that the first and second reels be used as a unit and the third reel as supplementary material.

Obstetric Roentgenography. 16 mm., black and white, sound, showing time 16 minutes. Prepared in 1950 by Paul C. Swenson, M.D., and T. L. Montgomery, M.D., Departments of Radiology, Obstetrics and Gynecology, Jefferson Medical College of Philadelphia. Procurable on loan from Film Library, Jefferson Medical College, 1025 Walnut Street, Philadelphia 7.

This motion picture describes the use of a modified Colcher-Sussman technic of pelvimetry and cephalometry with emphasis on the need for pelvic classification and careful clinical correlation in interpreting the observations. Emphasis is placed on the need for observation of the fetal-pelvic relationships at the time of labor.

The flat pelvis demonstration fails to mention the external characteristics, but this is not objectionable, inasmuch as the present trend is toward evaluating internal measurements, those which are necessary for the fetal head to pass through the pelvis. Some may question the cephalopelvic disproportion sequence in one section of the film which does not appear to exist. It seems to be an increased pelvic inclination instead of a disproportion. This sequence should be clarified. There may be exception to the statement "We are now going to do a sterile vaginal examination." This terminology should be discouraged.

With these exceptions the information given in the film is accurate. It should be suitable for general medical society meetings, general practitioners, medical students and nursing education. The photography ranges from poor to good. A black background in the early scenes showing several types of pelves would have been more suitable.

Your Friend in Blue. 16 mm., color, sound, showing time 30 minutes. Produced in 1950 by Division of Public Health Education, Minnesota Department of Health. Procurable on loan within the state of Minnesota and on purchase from Visual Education Dept., Minnesota Dept. of Health, University of Minnesota, Minneapolis.

This motion picture was produced to recruit more young women for training in the field of nursing and to interest local community groups in public health nursing service. It gives an over-all view of the education, functions and services of a public health nurse in a public health program. It also offers a picture of all the services provided by a public health nurse with more detail of the nursing care of the chronically ill. Services in the rural area and small town are shown in the nurse's opportunity to serve the general community. The film illustrates cooperation among several community agencies and shows the practicing physician in the promotion of a generalized public health nursing program. Though it does not imply that a nurse is associated with the health department, the latter is available for such assistance as she might need.

The film is well suited for showing to community groups for promotion of public health nursing services where such services do not exist; for use in high schools and colleges as a means of recruitment; to orient student nurses with a generalized community nursing program, and for medical student information. It could also be used to advantage in interpretation of the public health nurse's function to private physicians and personnel of community health agencies. The defects are largely omissions; however, a single film cannot include the whole story.

An explanation of the organization of the community that sponsors such programs would have been helpful. It must be remembered that this film was produced to develop interest in and to interpret the services of the public health nursing field. It was not intended for use as an instructional tool in the technics of nursing; however, the instructors in the school of nursing could supplement the film with demonstrations of nursing technics. In some places the color is very poor and underexposed. In general, the photography is fair to excellent. The narration is satisfactory and the sound good. At times the story moves rather slowly.

MEDICOLEGAL ABSTRACTS

Malpractice: Standards Applicable to Drugless Healers.—The plaintiff, administratrix of her husband's estate, filed suit for damages for his death, which was alleged to have been due to the malpractice of the defendant, a drugless healer. From an adverse judgment, the defendant appealed to the Supreme Court of Washington.

For several days the deceased had been bothered by nausea and a pain in his stomach. The muscles of the abdomen were somewhat rigid. At his wife's suggestion, he went to the defendant, a drugless healer, who was of the opinion that the deceased was undergoing a "reaction." After checking with a stethoscope, the defendant applied hot and cold packs and administered an electrical massage with a device known as a "sine wave." A form of laxative known to drugless healers as a "42" was also given. The same treatment was prescribed for the next 10 days, at the end of which time the plaintiff begged the defendant to call in a medical doctor. The defendant replied, "We don't need an M.D. If you call an M.D. he will kill him." The defendant also said he would "throw up" the case if a doctor was called. The next day, after the application of more hot and cold packs and a "sine wave" treatment, the deceased regurgitated matter that the defendant said was "pieces of the bowel." Defendant then massaged the deceased's abdomen, but when he left the house he told the plaintiff that she could now "call an M.D." He said, however, that he would not stay until an M.D. arrived, because he could not "be here when an M.D. comes." A physician, called to the plaintiff's home the next morning, immediately diagnosed her husband's condition as appendicitis and had him removed to a hospital, where he was given oxygen and treatment for shock. The deceased was moribund, and his abdomen was extremely rigid and distended. An operation was performed that same day, but no attempt at exploration was made after the incision was made, for the reason that a large quantity of pus was encountered, and the doctors thought it best simply to try to drain the matter present before any further surgery was attempted. The plaintiff's husband died within a week, and an autopsy indicated that death resulted from peritonitis and that the appendix had completely rotted off from the portion of the bowel to which it is normally attached.

The Supreme Court first stated four basic propositions applicable to the case. The first of these is that the defendant is not a doctor. An examination of all the statutes bearing on the subject, said the court, nowhere reveals any reference to drugless healers as "doctors," nor will the language used sustain even a remote inference that they are permitted to practice any phase of medicine or surgery. Limitation in the statutes specifically negates such an assumption. The second proposition is that drugless healers cannot qualify as expert witnesses as to matters in the general realm of medicine and surgery. The fields of drugless healing and surgery are not coextensive, and we are here concerned with the field in medicine and surgery that lies outside of the drugless healing field. The third proposition is that drugless healers do not belong to a school of medicine. They do not study in medical colleges as defined by statute, but in drugless healing schools. Thus, the particular school of their attendance is not a medical school, nor can such a school be said to adhere to a school of medicine, in the sense that a particular school is identified with a recognized and distinct approach to medical practice or opinion. This is so, notwithstanding the fact that some subjects taught in medical schools are also taught in the drugless healing school. The legislature required drugless healers to pursue certain studies in order that they would know enough not to injure patients, and to recognize cases where their limited methods are inefficacious and the services of a doctor are required. The fourth and last proposition is that one who does not have a license to practice medicine and surgery is, nevertheless, liable for malpractice when he assumes to act as a doctor and is to be judged as if he were a doctor because of those facts. The defendant's theory that a drugless healer is licensed to treat all human maladies and must be exonerated from all liability on his part, if he resorts only to the particular methods of his cult for determining the nature of diseases and the remedies therefor, no matter how serious the consequences, cannot be entertained. If there is a reasonable general agreement as to what is the proper medical treatment for a disease or an organic disorder, the question of whether the treatment, in a particular case, was correct must be determined by the testimony of expert witnesses from the medical field, who alone are qualified to speak. While it is true that a practitioner, such as the defendant, is not, in his limited field, required to be an insurer of results any more than a doctor of medicine, still, if he steps out of his limits and undertakes to treat a disorder for which, in the highest level of medical science, there is a generally recognized treatment, such interloper must be held accountable to the accepted standard of treatment.

The defendant first objected to a hypothetical question, which the court permitted to be answered. It is as follows: ". . . *if a patient presents symptoms of pain in the stomach and* throughout the abdomen, nausea and rigidity of muscles in the abdomen, with temperature, and is treated for a reaction for a period of 12 days, and his condition grows much worse, should a sanipractic doctor of average skill and experience of those of the same school of practice in Spokane, Wash., and with the use of ordinary care, be led to suspect that the patient is suffering from appendicitis?" It was, said the Supreme Court, incumbent on the plaintiff to show that there had been a wrong diagnosis and that it had been followed by treatment that was injurious. It was amply clear that the deceased had many of the characteristic symptoms of appendicitis and the defendant must have been aware that appendicitis was a probability, if not a certainty. If it was appendicitis, he had no right to treat it; and, if there was a possibility that it was appendicitis, he had no right to gamble with the deceased's life, on the theory that it might be something else. The gist of the defendant's argument is that a wrong rule of law was followed with regard to the admission of evidence and the effect allowed to be given to the evidence. His position is that a doctor does not incur liability for his mistakes, if he has used methods recognized and approved by those reasonably schooled in the profession, and that the testimony of other doctors that they would have followed a different course of treatment than that followed by the defendant, or a showing of a disagreement of doctors of equal skill and learning as to what the treatment should have been does not establish negligence. We may grant, said the court, that there has been such a rule applied between doctors, but we repeat that the defendant is not a doctor. The court should not apply such a rule to drugless healers, because it is obvious that their qualifications are so far inferior to those of a doctor that the law will conclusively presume that they are not on terms of equality which would entitle their opinions to cancel out the best medical opinion available. Should any court so hold, it would bring reproach on judicial processes by departing from the time-honored rules of evidence devoted to the most trustworthy ways of revealing truth, which has always admitted the best evidence available. The rationale of the rule is applicable only where doctors who are equal in their qualifications are concerned and where no recourse can be had to higher learning or greater experts.

The defendant next contended that the Appellate Court should have given a certain instruction requested by him. Among other things, this refused instruction said, "In this connection you are further instructed that if you find from a preponderance of the evidence in this case the deceased, Morris C. Kelly, or the plaintiff herein knew at the time they appointed the defendant that he belonged to a branch of the drugless school of healing which does not follow surgery, then the plaintiff in this case cannot charge the defendant with negligence in failing to advise or perform a surgical operation as treatment for which the said Morris C. Kelly was suffering." The defendant argued that without this paragraph the jury might have decided that it was the duty of the defendant, practicing as a drugless physician, to abandon his own method of drugless treatment in an appendicitis case and run to a surgeon for help. Such a finding by the jury would be justified as to the facts and correct as to the law, said the Supreme Court. A drugless healer is in a position of trust and confidence as regards his patient, and, if he knows or should know that any treatment he is permitted to use will be of no benefit to the patient, it is his duty to so advise. If there is another mode of treatment that is more likely to be successful, which treatment he does not have the right to give, it is his duty to send the patient to a doctor. The relationship between a physician and his patient is predicated on the proposition that the physician has special knowledge and skill in diagnosing and treating diseases and disorders. In the case at bar, the Supreme Court continued, the defendant knew or should have known that the treatment called for was beyond the scope of his license and ability. If a practitioner, such as the defendant, declines to discharge his duty to call in a qualified doctor when the situation obviously calls for it, he proceeds at his peril.

The defendant made much of the contention that the deceased had assumed the risk and was guilty of contributory negligence because he knew the defendant would neither operate nor advise an operation. The Supreme Court, however, said that, on the question of contributory negligence in such a case as the one at bar, the law is that it is not part of the duties of a patient to distrust his physician, or to set his own judgment against that of the expert whom he has employed to treat him, or to appeal to other physicians to ascertain if the physician is performing his duty properly. The very relation assumes trust and confidence on the part of the patient in the capacity and skill of the physician, and it would indeed require an unusual state of facts to render a person who is possessed of no medical skill guilty of contributory negligence just because he accepts the word of his physician and trusts the efficacy of the treatment prescribed by him. A patient has the right to rely on the professional skill of his physician, without calling others in to determine whether he really possesses such skill or not. The patient is not bound to call in another physician, unless he becomes fully aware that the physician has not been, and is not, giving proper treatment. On the basis of all the evidence, the court was of the opinion that the plaintiff was entitled to recovery and the judgment against the drugless healer was therefore affirmed.—*Kelly v. Carrol, et ux 219 P. (2d) 79 (Wash., 1950).*

Autopsies: When Court Should Permit Exhumation and Autopsy.—In an action for damages for the death of the plaintiff's husband following an automobile accident, the defendant filed a motion for permission to exhume the body of the deceased and to perform an autopsy thereon. From an order denying the motion, the defendant appealed to the Supreme Court of New Hampshire.

The defendant's motion alleged, among other things, that he was informed and believed that the deceased died of cancer and not as a result of the automobile accident in which he was involved; that permission to perform an autopsy was sought of and refused by the plaintiff; that unless an autopsy is performed the defendant will be deprived of information necessary to properly prepare and adequately defend the claims being presented on behalf of the plaintiff. The question before this court, said the Supreme Court, is whether the trial court's findings could reasonably be made on the evidence before him.

If the interests of justice demand it, the Supreme Court said, the trial court has the authority, in the exercise of a sound discretion, to order an autopsy. We agree that "the quiet of the grave, the repose of the dead, are not lightly to be disturbed. Good and substantial reasons must be shown before disinterment is sanctioned." However, the right to have a dead body remain unmolested is not an absolute one; it must yield where it conflicts with the public good or the demands of justice. In this case, continued the Supreme Court, the deceased had filed an action against the defendant for $25,000 after an automobile accident. He died 11 months after the accident, and his widow, the plaintiff, now claims his death, as well as his disability during the period between the accident and his death, was due to and caused by the accident. The defendant maintains that an autopsy is necessary in order to determine the nature of the deceased's injuries as well as the cause of his death.

It seems to us, said the Supreme Court, that an autopsy is very material to the defense of this action by the defendant; it may be vital, and the fact that the defendant might have other sources of evidence on the subject would not prevent his being granted the relief sought. We find no evidence in the record which could reasonably justify a denial of the defendant's motion for an autopsy under proper safeguards. Accordingly the action of the trial court denying the defendant the right to exhume the body of the deceased and to perform an autopsy thereon was reversed and permission therefor was granted.—*Kusky v. Laderbush,* 74 A (2d) 546 (New Hampshire 1950).

Paternity: Court's Right to Compel Submission to Blood Grouping Tests.—The plaintiff wife filed suit for divorce on the ground of desertion, and the defendant counterclaimed for divorce on the grounds of desertion and adultery, alleging that a child born to the plaintiff was not his daughter but was the result of an adulterous relationship. The defendant asked for an order requiring the plaintiff, the child and himself to submit to blood-grouping tests. The motion was heard in the superior court of New Jersey, chancery division.

The New Jersey statutes provide: "Whenever it shall be relevant in a civil action to determine the parentage or the identity of any child or other person, the court, by order, may direct that any party to the action and the person whose parentage or identity is involved submit to one or more blood-grouping tests, to be made by duly qualified physicians under such restrictions and directions as the court or judge shall deem proper." The court said that in its view the intent of the legislature in enacting the above statute reflected a recognition of "the theory that the evolution in practical affairs of life, whereby the progressive and scientific tendencies of the age are manifest in every other department of human endeavor, cannot be ignored in legal procedure, but that the law, in its effort to enforce justice by demonstrating a fact in issue, will allow evidence of those scientific processes which are the work of educated and skilful men in their various departments, and apply them to the demonstration of a fact."

In the first place, continued the court, it seems clear that the accuracy and worth of the tests has been abundantly shown. "On this point it is enough to cite the report of the American Medical Association's committee on Medicolegal Blood-Grouping Tests (*J. A. M. A.* **108**:2138 [June 19] 1937), which shows that, although such tests cannot prove paternity and cannot always disprove it, they can disprove it conclusively in a great many cases provided they are administered by specially qualified experts." In a prior case decided by the Supreme Judicial Court of Maine the worth of these tests was recognized and it was held that where exclusion of parentage was shown by competently given tests the evidence was conclusive (*Jordan v. Mace,* 69 A [2d] 670; *J. A. M. A.* 142:750 [March 11] 1950). To the same effect is a recent case decided by the New York Appellate Division (*Commissioner of Welfare ex rel v. Costonie,* 97 N. Y. S. [2d] 804; *J. A. M. A.* 144:573 [Oct. 14] 1950). If blood tests are accurate, relevant and on their face apparently authorized by statute, continued the court, an order for such a test on proper terms should be granted.

Continuing, the court concluded that a case such as this comes within the words of the statute that "Whenever it shall be relevant in a civil action to determine the parentage or the identity of any child . . . (emphasis added)" and such a holding is not a violation of the Constitution. The health of our judicial system, depending as it does on the finding of truth so that justice may be done, is of equal importance with the physical health of the community and a blood-grouping test, made by skilled physicians, does not constitute the mythical nose of the camel under the tent which will be followed by such extreme measures as the trepanning of the skull of a witness. Accordingly the defendant's motion requiring the plaintiff, the defendant and the child to submit to blood tests by two physicians duly qualified by training and experience was granted.—*Anthony vs. Anthony,* 74 A (2d) 919 (New Jersey 1950).

MEDICOLEGAL ABSTRACTS

Malpractice: Standards Applicable to Drugless Healers.—The plaintiff, administratrix of her husband's estate, filed suit for damages for his death, which was alleged to have been due to the malpractice of the defendant, a drugless healer. From an adverse judgment, the defendant appealed to the Supreme Court of Washington.

For several days the deceased had been bothered by nausea and a pain in his stomach. The muscles of the abdomen were somewhat rigid. At his wife's suggestion, he went to the defendant, a drugless healer, who was of the opinion that the deceased was undergoing a "reaction." After checking with a stethoscope, the defendant applied hot and cold packs and administered an electrical massage with a device known as a "sine wave." A form of laxative known to drugless healers as a "42" was also given. The same treatment was prescribed for the next 10 days, at the end of which time the plaintiff begged the defendant to call in a medical doctor. The defendant replied, "We don't need an M.D. If you call an M.D. he will kill him." The defendant also said he would "throw up" the case if a doctor was called. The next day, after the application of more hot and cold packs and a "sine wave" treatment, the deceased regurgitated matter that the defendant said was "pieces of the bowel." Defendant then massaged the deceased's abdomen, but when he left the house he told the plaintiff that she could now "call an M.D." He said, however, that he would not stay until an M.D. arrived, because he could not "be here when an M.D. comes." A physician, called to the plaintiff's home the next morning, immediately diagnosed her husband's condition as appendicitis and had him removed to a hospital, where he was given oxygen and treatment for shock. The deceased was moribund, and his abdomen was extremely rigid and distended. An operation was performed that same day, but no attempt at exploration was made after the incision was made, for the reason that a large quantity of pus was encountered, and the doctors thought it best simply to try to drain the matter present before any further surgery was attempted. The plaintiff's husband died within a week, and an autopsy indicated that death resulted from peritonitis and that the appendix had completely rotted off from the portion of the bowel to which it is normally attached.

The Supreme Court first stated four basic propositions applicable to the case. The first of these is that the defendant is not a doctor. An examination of all the statutes bearing on the subject, said the court, nowhere reveals any reference to drugless healers as "doctors," nor will the language used sustain even a remote inference that they are permitted to practice any phase of medicine or surgery. Limitation in the statutes specifically negates such an assumption. The second proposition is that drugless healers cannot qualify as expert witnesses as to matters in the general realm of medicine and surgery. The fields of drugless healing and surgery are not coextensive, and we are here concerned with the field in medicine and surgery that lies outside of the drugless healing field. The third proposition is that drugless healers do not belong to a school of medicine. They do not study in medical colleges as defined by statute, but in drugless healing schools. Thus, the particular school of their attendance is not a medical school, nor can such a school be said to adhere to a school of medicine, in the sense that a particular school is identified with a recognized and distinct approach to medical practice or opinion. This is so, notwithstanding the fact that some subjects taught in medical schools are also taught in the drugless healing school. The legislature required drugless healers to pursue certain studies in order that they would know enough not to injure patients, and to recognize cases where their limited methods are inefficacious and the services of a doctor are required. The fourth and last proposition is that one who does not have a license to practice medicine and surgery is, nevertheless, liable for malpractice when he assumes to act as a doctor and is to be judged as if he were a doctor because of those facts. The defendant's theory that a drugless healer is licensed to treat all human maladies and must be exonerated from all liability on his part, if he resorts only to the particular methods of his cult for determining the nature of diseases and the remedies therefor, no matter how serious the consequences, cannot be entertained. If there is a reasonable general agreement as to what is the proper medical treatment for a disease or an organic disorder, the question of whether the treatment, in a particular case, was correct must be determined by the testimony of expert witnesses from the medical field, who alone are qualified to speak. While it is true that a practitioner, such as the defendant, is not, in his limited field, required to be an insurer of results any more than a doctor of medicine, still, if he steps out of his limits and undertakes to treat a disorder for which, in the highest level of medical science, there is a generally recognized treatment, such interloper must be held accountable to the accepted standard of treatment.

The defendant first objected to a hypothetical question, which the court permitted to be answered. It is as follows: ". . . if a patient presents symptoms of pain in the stomach and throughout the abdomen, nausea and rigidity of muscles in the abdomen, with temperature, and is treated for a reaction for a period of 12 days, and his condition grows much worse, should a sanipractic doctor of average skill and experience of those of the same school of practice in Spokane, Wash., and with the use of ordinary care, be led to suspect that the patient is suffering from appendicitis?" It was, said the Supreme Court, incumbent on the plaintiff to show that there had been a wrong diagnosis and that it had been followed by treatment that was injurious. It was amply clear that the deceased had many of the characteristic symptoms of appendicitis and the defendant must have been aware that appendicitis was a probability, if not a certainty. If it was appendicitis, he had no right to treat it; and, if there was a possibility that it was appendicitis, he had no right to gamble with the deceased's life, on the theory that it might be something else. The gist of the defendant's argument is that a wrong rule of law was followed with regard to the admission of evidence and the effect allowed to be given to the evidence. His position is that a doctor does not incur liability for his mistakes, if he has used methods recognized and approved by those reasonably schooled in the profession, and that the testimony of other doctors that they would have followed a different course of treatment than that followed by the defendant, or a showing of a disagreement of doctors of equal skill and learning as to what the treatment should have been does not establish negligence. We may grant, said the court, that there has been such a rule applied between doctors, but we repeat that the defendant is not a doctor. The court should not apply such a rule to drugless healers, because it is obvious that their qualifications are so far inferior to those of a doctor that the law will conclusively presume that they are not on terms of equality which would entitle their opinions to cancel out the best medical opinion available. Should any court so hold, it would bring reproach on judicial processes by departing from the time-honored rules of evidence devoted to the most trustworthy ways of revealing truth, which has always admitted the best evidence available. The rationale of the rule is applicable only where doctors who are equal in their qualifications are concerned and where no recourse can be had to higher learning or greater experts.

The defendant next contended that the Appellate Court should have given a certain instruction requested by him. Among other things, this refused instruction said, "In this connection you are further instructed that if you find from a preponderance of the evidence in this case the deceased, Morris C. Kelly, or the plaintiff herein knew at the time they appointed the defendant that he belonged to a branch of the drugless school of healing which does not follow surgery, then the plaintiff in this case cannot charge the defendant with negligence in failing to advise or perform a surgical operation as treatment for which the said Morris C. Kelly was suffering." The defendant argued

Dermatomyositis and Lupus Erythematosus —The difficulty encountered in differentiating acute disseminated lupus erythematosus from dermatomyositis prompted Madden and Karon to evaluate muscle biopsies done on patients with these diseases, and, because Hargraves found the so-called L E cell in bone marrow preparations from patients with acute disseminated lupus erythematosus, they also searched for such cells The authors compare and correlate observations made on 27 patients, eight of whom had dermatomyositis and 19 of whom had lupus erythematosus The 12 biopsies done on eight patients with dermatomyositis showed varying degrees of nodular myositis The myositis was severer in the acute cases and decreased in intensity as the disease became chronic Nodular myositis was seen in only six of 21 biopsy specimens from patients with lupus erythematosus The myositis was severe in only one patient, who also had rheumatic fever, and mild in the other patients, who also had arthralgia rheumatic pains or rheumatoid arthritis Nodular myositis was not seen in a single case of lupus erythematosus that was not associated with rheumatic fever, arthralgia, rheumatic pains or arthritis Nodular myositis was not seen in chronic or subacute lupus erythematosus Degenerative processes in muscles appeared in all except one patient with dermatomyositis, but in only six of 19 cases of lupus erythematosus Degenerative processes in muscles by themselves are of little assistance in diagnosis Twenty one sternal bone marrow examinations with special reference to L E cells were made in five cases of dermatomyositis, eight cases of acute disseminated lupus erythematosus and six cases of subacute lupus erythematosus L E cells were not found in the bone marrow of patients with dermatomyositis or subacute or chronic lupus erythematosus, and they were found in only half the patients with acute disseminated lupus erythematosus The L E cells are a valuable diagnostic aid, especially in cases of acute disseminated lupus erythematosus without cutaneous manifestation Bone marrow examinations and muscle biopsies should be an aid in making the differentiation between dermatomyositis and lupus erythematosus

Streptomycin in Granuloma Inguinale —Pariser and his associates present observations on 76 patients with granuloma inguinale who were treated with streptomycin The lesions of 80 per cent of their patients healed with a dosage of 18 Gm of streptomycin given orally in divided doses of 0 6 Gm every four hours over a five day period Treatment failures could be reduced to approximately 4 per cent by retreatment with 4 Gm per day over a period of 10 days Although the oral use of aureomycin and chloramphenicol may cause healing of lesions resistant to intensive therapy with streptomycin the experience of these authors with the drugs is too limited to permit one to draw conclusions

Chemosurgical Treatment of Melanoma —Mohs points out that in the treatment of epithelioma the "silent" extensions from the main mass of cancer can be traced and eradicated by means of multiple microscopically controlled excisions which characterize the chemosurgical method In the treatment of melanoma however, this microscopic control would seem to be of more limited value because often there is a discontinuous, embolic mode of spread into the peritumoral lymphatics and beyond The author analyzes results obtained with his chemosurgical method in 20 patients with melanoma who have been observed for five or more years or until death The primary melanoma was more than 3 cm in diameter in 10 of the patients, 12 of the patients had received surgical or radiation treatment before the chemosurgical method was applied, and 10 had palpable enlargement of the lymph nodes at the time chemosurgical treatment was instituted Seven of the 20 patients survived and were well for more than five years after treatment, one of them for more than 12 years Nine of the remaining 13 patients died as the result of metastases, the other four died of either undetermined causes, "stroke" or pneumonia These results compare favorably with those obtained by others using more radical methods The chemosurgical method completely removes cutaneous melanomas It is necessary to remove an additional zone of tissue after a melanoma free level has been reached because of the danger of satellite deposits in the surrounding lymphatics The width of this extra zone varies in proportion to the size and the malignancy of the melanoma The regional nodes are surgically dissected if enlarged or if the size and degree of malignancy of the primary lesion warrant a prophylactic dissection of nonpalpable nodes

Crystalline Ester Cholesterol and Cortical Renal Tumors —In this extensive discussion on cholesterol and the renal cortex, Leary pays particular attention to the relation of crystalline ester cholesterol to the cortical renal tumors occurring in adults Miniature tumors were collected at the Mallory Institute of Pathology over a period of years Solitary growths, nodules appearing in small numbers and, particularly, kidneys showing large numbers of nodules were studied Evidence is presented that the crystalline ester cholesterol deposited in the

CURRENT MEDICAL LITERATURE

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1939 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Biopsy in Cirrhosis of Liver.—Popper and co-workers correlated clinical and laboratory observations with various histopathological features, such as liver cell damage, coagulation necrosis, fatty metamorphosis, focal necrosis and leukocytic reactions, in 97 liver biopsy specimens, obtained from 70 patients with cirrhosis. Diffuse liver cell damage showed the best correlation with clinical and with biochemical activity. The other features showed less correlation, which, when observed, was best explained by the concomitant presence of liver cell damage. This suggests that liver cell damage is the most important factor in determining the clinical activity in cirrhosis. A series of hepatic tests was performed on all patients within 48 hours to seven days of the biopsy. Increased cephalin flocculation and thymol turbidity tests appeared best to indicate the presence of diffuse liver cell damage in cirrhosis. These were followed by serum albumin reduction and to a lesser degree by serum globulin elevation and reduction of albumin-globulin ratio. Patients with an alcoholic history revealed, in general, less liver cell damage and more fatty metamorphosis than those without such a history. Ascites coincided most with scarring and other phenomena associated with fibroplasia and inflammation in the portal triads and in the connective tissue trabeculae. The type of cirrhosis associated with jaundice failed to reveal specific morphological characteristics except for the presence of static bile pigment. The morphological analysis did not reveal a structural basis for the pronounced jaundice or for the intrahepatic interruption of the biliary flow in cirrhosis.

Acute Pancreatic Necrosis.—Roberts and co-workers analyzed the clinical records and postmortem observations in 25 fatal cases of acute pancreatic necrosis in 13 men and 12 women between the ages of 26 and 73 years. The average age of the patients was 51.9 years. Sixteen patients, 11 women and five men, were described as obese. A record of the past consumption of alcohol was available in 10 patients, two of whom admitted excessive drinking and two others moderate drinking. No common causative denominator was immediately apparent. Most impressive was the coincidence of proved disease of the biliary tract in 21 of the 23 patients in which a description of the gross appearance of the biliary tract was available. Eighteen of these 23 patients had biliary stones. The disease occurs in both sexes and is most frequent in middle life. It is especially common in the obese and in alcoholics and often is precipitated after a meal or an alcoholic debauch. Its onset is usually sudden with severe constant upper abdominal pain, often extending to the back. Ordinarily the pain persists for at least several hours and often is not relieved by the usual doses of narcotics. Nausea and vomiting commonly occur promptly. A subnormal to normal temperature, low pulse rate and normal blood pressure are noted initially in most instances. Shock may develop early, late or not at all. Moderate to pronounced epigastric tenderness with only slight to moderate rigidity is usual. Subsequent distention is common and jaundice frequent. Conclusive laboratory assistance may be obtained by the demonstration of elevated serum levels of amylase and lipase in almost all cases observed early. Albuminuria is noted in most patients; sugar levels up to 20 per cent have been noted. Diagnosis, formerly difficult, is possible in most cases as a result of increased knowledge and awareness of the disease, coupled with the substantiating laboratory procedures now available.

Effect of ACTH in Glaucoma.—Blake and his associates state that pituitary adrenocorticotropic hormone (ACTH) had no appreciable effect on the intraocular pressure in their first two cases of primary glaucoma. In the third patient uveitis in one eye appeared to be developing into primary bilateral glaucoma. Here the acutely raised tension and inflammation responded promptly in the one eye. The fourth patient who had early uveitis with a secondary rise in tension experienced a remarkable clinical improvement within 48 hours, including a definite drop in tension. The fifth case was one of chronic primary glaucoma, which, after eight days of treatment, showed no significant drop in pressure. It would appear that pituitary adrenocorticotropic hormone had no demonstrable effect in the reduction of intraocular pressure in primary glaucoma. Since increased intraocular pressure accompanying anterior uveal disease showed a drop in tension and subsidence of the inflammatory process, it is suggested that, if pituitary adrenocorticotropic hormone becomes more readily available, it may be useful in the differentiation between primary and so-called secondary glaucoma.

Crystalline Ester Cholesterol and Cortical Renal Tumors—In this extensive discussion on cholesterol and the renal cortex, Leary pays particular attention to the relation of crystalline ester cholesterol to the cortical renal tumors occurring in adults Miniature tumors were collected at the Mallory Institute of Pathology over a period of years Solitary growths, nodules appearing in small numbers and, particularly, kidneys showing large numbers of nodules were studied Evidence is presented that the crystalline ester cholesterol deposited in the epithelium of renal convoluted tubules in adults, particularly in those afflicted with nephrosclerosis, is the stimulating agent responsible for the growth of benign cortical adenomas in man. Removal of the crystalline ester cholesterol is followed by a cessation of the growth of such adenomas, which then revert to inactive tubular adenomas. It is generally accepted that adult renal cortical adenocarcinomas have their origin in benign adenomas. Recent experimental chemical studies support the thesis that cholesterol by itself or in combination with small amounts of a cocarcinogen is the cause of sarcoma induced in mice by the injection of cholesterol-rich extracts of human or animal tissue. The combined histochemical and chemical evidence leaves little doubt that cholesterol is intimately related to certain human and experimental tumors.

Surgical Treatment of Tuberculous Pericarditis.—Holman points out that tuberculous pericarditis poses the twofold problem of controlling infection and of correcting the mechanical interference with the flow of blood. He reviews four cases of tuberculous pericarditis cured or greatly improved by pericardectomy. The disease is characterized by a prolonged course exhibiting in the acute stage chills, sweats, fever, rapid pulse rate, dyspnea, increased sedimentation rate, leukocytosis, anemia, pericardial friction rub and pericardial effusion sufficient at times to produce compression of the heart and the superior and inferior venae cavae as shown by increased venous pressure, by fluoroscopic absence of ventricular pulsations and by a reduced voltage in the QRS complex and inverted T waves in the electrocardiogram. Such effusion may persist or may subside as shown by a reduction in the size of the cardiac shadow. In two cases this disappearance of pericardial effusion took place within three weeks after complete bed rest but was followed promptly by signs of cardiac compression due to contracture of the inflamed and thickened pericardium. Pericardiectomy should be considered at the time of pericardial effusion, particularly if compression of the heart and the superior and inferior venae cavae is present. In a very ill patient with pericardial effusion such decompression might be best effected by removal of the left sixth costal cartilage for evacuation and drainage of the pericardium, followed at a second stage, 10 to 20 days later, by median sternotomy and radical pericardiectomy. Despite the improvement following the first operation, the second operation should be performed without fail. Radical pericardiectomy in the four cases reviewed here resulted in apparent cure in three and in progressive improvement in one. Primary healing occurred in all operative areas, despite the presence of tubercle bacilli in the diseased pericardium. The beneficient influence of streptomycin and penicillin on the results is conceded.

Stellate Block in Intracranial Pathologic States.—According to Naffziger and Adams it is probable that cerebral vasospasm may either initiate or contribute to such neurological disorders as hemiplegia, aphasia and hemianopsia. Realizing this possibility, Leriche and Fontaine proposed interruption of the intracranial vascular sympathetic innervation by procaine hydrochloride block of the stellate ganglion. The improvement following stellate block in a patient with complete hemiplegia induced Naffziger and Adams to use this method in similar cases. They were reluctant to block the stellate ganglion when history or presence of blood in the cerebrospinal fluid indicated an acute cerebral hemorrhage, fearing that the bleeding might be augmented and the brain damage increased. In such cases they waited until bleeding (bloody cerebrospinal fluid) had subsided. An anterior approach to the region of the stellate ganglion was used in all instances. Two to 3 cc. of 1 per cent procaine hydrochloride was injected. The number and frequency of injections varied depending on the condition of the patient and the result obtained with the initial injection. One or two injections sufficed in many patients. Others required injection as often as three times daily for several days. Of the 155 patients with cerebrovascular accidents who were treated with stellate block, 91 made a complete clinical recovery, 37 made a partial recovery and in the remaining 27 the results were poor, in that they showed no improvement or died. Stellate block was employed also in 70 patients with acute neurologic deficits associated with trauma or intracranial operations. The results in these 70 patients without cerebrovascular disorders were good in 30, fair in 30 and poor in 10. The procedure has been extended to patients with neurological defects remaining as a result of prior cerebrovascular accidents. The authors observed improvement occurring as late as six years after the original vascular insult.

Continuous Caudal or Spinal Anesthesia in Treatment of Eclampsia.—Kennedy and his associates report the histories of four patients with eclamptogenic toxemia of pregnancy who were treated with continuous caudal and/or continuous spinal anesthesia supplemented by routine conservative medical management. In two of the cases the convulsive seizures occurred before delivery, while in the other two they occurred during the immediate postpartum period. One patient was treated by continuous caudal, one by continuous caudal later replaced by continuous spinal and two by continuous spinal anesthesia. The minimal length of time a patient was kept under continuous anesthesia was 13 hours, while the longest administration was 96 hours. Piperocaine hydrochloride was the anesthetic agent used in all cases except one, in which tetracaine hydrochloride was employed for a short time. The minimal caudal dose was 1,125 mg. and the maximal 3,525 mg.; the minimal dosage under continuous spinal was 622.5 mg. and the maximal 3,810 mg. Two patients responded with diuresis and alleviation of proteinuria within 12 hours after institution of therapy, while in the other two cases improvement was not definitely assured until 24 to 36 hours later. Three patients showed a definite decrease in hypertension during therapy; only one failed to show the drop in blood pressure shown by the others. Two patients were discharged with blood pressures slightly exceeding the arbitrary standards of 140/90. The authors used this treatment successfully in a large number of patients with preeclampsia and in many pregnant women with hypertensive cardiovascular disease. They do not wish to imply that this treatment will cure all eclamptic patients, but in their experience it is the best treatment available at the present time. They warn that this type of anesthesia is a powerful but dangerous therapeutic measure and should be used only by physicians thoroughly trained in its administration.

Desoxycorticosterone Acetate and Ascorbic Acid in Rheumatoid Arthritis.—Graham, Hunt and Mowat point out that Lewin and Wassén reported that in a majority of patients with rheumatoid arthritis a dramatic decrease in pain and stiffness followed the parenteral administration of desoxycorticosterone acetate and ascorbic acid. Ten subsequent reports have given rise to controversy since five of them seemed to confirm the observations of Lewin and Wassén whereas the others, with the same technic employed, reported no significant response. Graham and his associates describe their observations on 37 patients with rheumatoid arthritis, 10 with ankylosing (Marie-Strümpell) spondylitis and three with acute gouty arthritis who were treated with intramuscular administration of desoxycorticosterone acetate and ascorbic acid combined. Treatment was continued for one to 14 days. In most of the patients no obvious change, subjective or objective, was noted. A few, however, described temporary, sometimes dramatic, relief from stiffness and pain, especially after the first injection. In view of the psychological factors involved, such temporary improvement must be interpreted with caution. Treatment with desoxycorticosterone acetate and ascorbic acid was found to have no effect on the activity or the progression of the diseases as shown by the degree of swelling, the erythrocyte sedimentation rate and serum protein fractions. The injection of desoxycorticosterone acetate and ascorbic acid did not have any effect on the total circulating eosinophil counts or glucose tolerance curves, such as are found after therapy with cortisone or pituitary adrenocorticotropic hormone.

Convulsions and Hemiplegia in Prophylaxis of Pertussis.—Grace describes two cases in which severe untoward reactions followed administration of multiple antigens for prophylactic immunization. The preparation used was a fluid form of diphtheria toxoid, pertussis vaccine and tetanus toxoid (combined). The dose given was 0.5 cc. which contained approximately 11,250,000,000 killed bacilli from strains in phase I Hemophilus pertussis, 15 L.F.D. of diphtheria toxoid and 5 L.F.D. of tetanus toxoid. The pertussis component of the preparation is considered responsible for the adverse effects produced. In the first case an explosive episode occurred with severe prolonged convulsive seizure and right-sided hemiplegia. Sequelae remain which are indicative of permanent cerebral damage. In the second case the reaction was less violent; complete recovery followed the convulsive seizure. The authors cite other reports of similar untoward effects occurring with pertussis preparations of various types alone or in combinations with other antigens and manufactured by different companies. They direct attention to the serious results which may occur when pertussis antigen is administered to a subject who is predisposed to the convulsive state.

Who Protects Blue Cross?—Howley feels that the medical profession has been slow to realize that in its hands, almost exclusively, rests the success of voluntary prepayment of the costs of medical care. Blue Cross has been caught between the upper and nether millstones of spiraling costs and increasing utilization. As the utilization rate rises, the subscribers must pay more, and the day may come when Blue Cross will be too expensive for poor people; when that day comes, there will be compulsory health insurance. Hawley pleads that Blue Cross be protected against being priced out of the market. He suggests among other factors elimination of services which are purely luxuries and which do not contribute significantly to the recovery of patients. Hospital administrators and pathologists must bring to the attention of the staff as a whole the unnecessary services that are being ordered for patients. The author deplores the curious defect in public morality which makes it no crime to defraud an insurance company. Many persons who would be horrified at the thought of stealing one penny from a fellow man have not the slightest compunction about taking money under false pretenses from an insurance company. Patients may demand hospitalization as a luxury rather than as a necessity. On the excuse that the home is being renovated or that the cook will not return for several days, the patient may ask to remain in the hospital beyond the time that hospital care is necessary. It is not easy for the physician to pit his own sense of right and wrong against a patient's capricious desire. It should be made easier for him by Blue Cross members' awareness that each day of unnecessary utilization of their benefits must be paid for by increased cost of their own protection as well as that of all other Blue Cross members.

Autopsy Incidence of Pulmonary Embolism in Tuberculosis T J Moran —p 171

Shrunken Right Middle Lobe —The Rubins report on 16 patients with a shrunken right middle lobe, a condition referred to by some as the "middle lobe syndrome" The right middle lobe is most subject to collapse This is due to the fact that its bronchus is especially vulnerable to compression and invasion by bronchopulmonary lymph nodes, the latter draining the lower as well as the middle lobe It is possible that middle lobe shrinkage occurs as a result of pressure exerted on bronchi by cicatrizing nontuberculous lymph nodes but the analysis of the histories and roentgen observations in these 16 cases suggest that in each instance a preexisting tuberculous focus probably in regional lymph nodes led to the involvement of the middle lobe The symptoms produced by the shrunken middle lobe are usually like those of bronchitis but there are intercurrent episodes of pulmonary infections or hemoptysis Usually the course is mild The true cause may be overlooked or the symptoms erroneously ascribed to pleuropericardial adhesions or interlobar pleurisy The diagnosis can be made by roentgenography in the posteroanterior right lateral and lordotic projections The shrunken lobe appears as a triangular or roughly quadrilateral density at the root of the lung Tomography is helpful Bronchoscopy is essential in the determination as to whether one is dealing with bronchiogenic neoplasm Bronchography is necessary for establishment of the presence of bronchiectasis Treatment consists of excision of the involved lobe unless the age and condition of the patient contraindicate surgery

Visual Complications of Diabetes Mellitus —Knauer says that, as the life of diabetic patients is prolonged, diabetes mellitus may top the list of causes of loss of vision At least 40 per cent of patients who have had diabetes mellitus for 15 years will have some form of retinopathy The percentage rises to 85 for the group who have had this disease for 25 years or more Ophthalmologists should record the time at which diabetes mellitus was first diagnosed in cases of diabetic retinopathy The patients should be told to report visual disturbances The diabetic changes in the retina, which are usually bilateral, occur in the area between the upper and lower temporal vessels and the region surrounding the optic nerve head Numerous so called small round deeply situated hemorrhages or hemorrhagic spots occur, and, in addition, there are usually small exudates Treatment with rutin seems to improve the capillary fragility but not the diabetic retinal lesions The hope that early and physiological control of the diabetes may avert later hopeless and disastrous complications is gaining ground By close cooperation between the internist and the ophthalmologist it may be possible to evolve a method whereby retinal complications can be avoided and blindness from diabetes eliminated The author stresses that patients who have had diabetes mellitus for 10 years or more should undergo ocular examination at regular and relatively frequent intervals and the fundus of the eye should be carefully examined

Granuloma of Larynx Following Intratracheal Anesthesia —Wattles believes that granuloma of the larynx following intratracheal anesthesia is more frequent than the few reported cases seem to indicate Of the 22 cases that had been recorded to the end of September 1949 more than three fourths (17) were in women The favored site appears to be the posterior portion of the vocal cord or on or near the vocal process of the arytenoid cartilage, where the lesion is subject to trauma in the use of the voice Chronic nonspecific inflammation characterizes the condition There may be polypoid masses composed of new granulation tissue richly supplied with blood vessels and covered with inflammatory exudate or small, hard, fibrous nodules composed of inflammatory fibrous tissue with few blood vessels, the whole covered with epithelium Granulation tissue may surround the cartilage of the vocal process, the cartilage may be found in the floor of the ulcer or may be loose in the granuloma The cause is obviously mechanical The intratracheal tube, by pressure necrosis or trauma, produces an ulcer of the larynx The chief symptom is hoarseness Other complaints are discomfort in the larynx, pain extending to the ear and occasionally hemoptysis and chronic cough Dyspnea and cyanosis may make an emergency operation necessary Treatment consists of removal of the granuloma Recurrence of the granuloma may require repeated excision The lesion frequently occurs bilaterally, as in the case which the author observed Every effort should be made to avoid this complication through gentleness during intubation, careful examination of the larynx preoperatively and postoperatively and appropriate treatment of abrasions Surgeons should be aware of this possible complication, and, when a patient, particularly a woman, complains of hoarseness loss of voice, laryngeal pain or discomfort in the throat after tracheal intubation, the larynx should be examined with this sequela in mind

Effect of Atropine on Gastric Functions —Gill and Jessup describe studies made on six hospitalized male patients with uncomplicated duodenal ulcer in order to determine the effects on certain functions of the stomach of atropine sulfate given by mouth. A dye dilution technic was employed to calculate the rates of gastric secretion and pyloric evacuation. Definite diminution in free and total acid production rate of gastric secretion and rate of pyloric evacuation was observed while the patients were receiving atropine. These studies corroborate the generally held concept that the parasympathetic nervous system, through the vagus nerves, stimulates secretion and motility of the human stomach and that atropine is an effective inhibitor of this action. Results with atropine are similar to the immediate results of vagotomy. The large doses of atropine used in this study caused blurring of vision and dryness of the mouth. The fact that a dose of 2.4 mg. of atropine sulfate given every four hours produced no greater decrease in acid or motility than a dose of 1.2 mg. suggests that atropine in even smaller doses might be sufficient to obtain the desired results. Caution is advisable in the use of atropine in older patients with cardiovascular disease or increased intraocular tension.

Salt Retention in Cirrhosis of Liver.—Goodyer and his associates infused 500 cc. of a 5 per cent solution of sodium chloride into normal adults and into patients with cirrhosis, most of whom had normal glomerular filtration rates and renal plasma flows. All subjects were deprived of food and water for 12 hours before the infusion and for six to eight hours thereafter. The concentrations of serum sodium rose about 10 milliequivalents per liter during the infusions in all experiments and remained elevated during the subsequent period of water deprivation, during which time the normal subjects and two patients with cirrhosis without ascites or edema excreted 12 to 54 per cent of the administered sodium. The concentration of sodium in their urine increased to as much as 267 milliequivalents per liter and the rate of sodium excretion increased greatly. In contrast during the same period, the cirrhotic patients with edema and/or ascites excreted 0.2 to 10 per cent of the administered sodium. The concentration of sodium in their urine increased to a maximum of 102 milliequivalents per liter, and the rate of sodium excretion increased only minimally. Potassium excretion increased in most patients coincidentally with the sodium uresis. The authors regard the results of these tests as evidence of a specific impairment of the renal mechanism for the excretion of sodium in patients in whom hepatic cirrhosis is accompanied with edema and/or ascites. It appears that dietary sodium is retained by the kidneys of these patients as a result of the increased tubular reabsorption, the stimulus for which remains obscure.

Iron Metabolism: Hematopoiesis Following Phlebotomy.—In the studies reported by Finch and his associates, dogs and men were repeatedly subjected to phlebotomy over a period of several months. The bleeding produced anemia and thereby stimulated hematopoiesis. The removal of 3,500 cc. of blood in normal subjects over a period of seven weeks resulted in, first, an increased rate of blood formation and later, as iron depletion became manifest, a retardation of hematopoiesis. While on a normal diet without supplemental iron therapy, the subjects recovered from the anemia in two months. The serum iron level remained depressed, suggesting a deficiency in iron stores over a longer period. Hematopoiesis was severely curtailed in persons with depleted stores of iron. In patients with excessive tissue iron including those with hemochromatosis, blood production continued at an accelerated rate. Weekly phlebotomies of 500 cc. could be continued for several months without the development of significant anemia. From data obtained on phlebotomized patients with polycythemia vera, the maximal amount of iron available from the diet for hemoglobin production seems to be 2 to 4 mg. per day. This would contribute but little to the total iron mobilized under the conditions of the experiment. These observations indicate that the rate of blood regeneration following phlebotomy is dependent chiefly on available body stores of iron.

Q Fever: Recovery of Coxiella Burnetii from Dust.—Coxiella burnetii, the causal organism of Q fever, was found in California in the milk of infected dairy cattle, sheep and goats. Many human cases of Q fever occurring in California could be tracted neither to the use of raw milk nor to contact with dairy cattle, sheep or goats. It is possible that infection may arise from air-borne dust originating in environments contaminated with the body secretions or excreta of infected livestock. This report presents data on initial experiments conducted to ascertain the presence of Coxiella burnetii in dust from such environments The authors recovered Coxiella burnetii from dust-laden air on a dairy in southern California and from dust-laden air on a sheep ranch in northern California Thus it has been demonstrated that Coxiella burnetii may be present in the dust laden air on premises harboring infected domestic livestock The possibility thus exists that human (or animal) infection may be acquired by exposure to contaminated air Air borne dissemination of the rickettsiae might offer an explanation for some of the outbreaks and sporadic cases of Q fever which have occurred in the absence of direct contact with infected livestock

Addiction to Analgesics and Barbiturates —Isbell and Fraser review the literature of the last decade on addiction to analgesic drugs They found that every drug in the morphine series which is an effective analgesic is also capable of producing addiction and that the likelihood of producing addiction generally parellels the analgesic potencies of the morphine drugs Addiction to meperidine hydrochloride is fairly common, and physical dependence can be developed in persons who have never been previously addicted to any other analgesic drug The spinal cord, and probably other parts of the central nervous system, are involved in physical dependence on morphine This dependence is not entirely due to changes in the autonomic nervous system Addiction to morphine and other analgesics causes a general slowing up of the electroencephalogram No permanent anatomic damage is done to the central nervous system, nor is there permanent impairment of intelligence Treatment of morphine addiction involves withdrawal of the drug followed by a long period of rehabilitative and psychiatric therapy Addiction to barbiturates is far more dangerous and harmful than is addiction to morphine The clinical picture of chronic barbiturate intoxication resembles that of chronic intoxication with alcohol and is characterized by impairment of mental ability, impairment of emotional control, psychic regression and dangerous neurological symptoms Withdrawal of barbiturates is followed by a severe type of abstinence syndrome which is characterized by convulsions and delirium Treatment of chronic barbiturate intoxication is the same as for morphine addiction

Tumors of the Thymus.—Seybold and co-workers report 45 patients 28 women and 17 men between the ages of 16 and 68, with thymoma Tissue was made available for study by surgical removal or by necropsy Thymoma was defined as a specific tumor of the thymus characterized by the presence of both thymic epithelial and thymocytic cells in varying proportions The thymoma was associated with myasthenia gravis in 34 patients (75 6 per cent), 22 of whom were aged over 40 *Eleven patients (25 per cent)* had no evidence of myasthenia gravis at the time they were operated on and subsequently had no symptoms of this disease Patients with myasthenia gravis or suspected of having it should be examined by roentgenoscopy and by posteroanterior and lateral roentgenography. Characteristically, thymomas occur in the anterior mediastinum in a position anterior to the aortic arch and the base of the heart Some of the tumors contained calcium in quantities sufficient to be apparent roentgenologically Peculiar features which would permit a pathological diagnosis on the basis of roentgenologic observations were lacking Three fourths of the thymomas had a distinct fibrous capsule, while 10 had broken through their capsule to invade adjacent structures and two had spread to pleural surfaces as nodular implants of the tumor There was no evidence of embolic, lymphogenous or hematogenous metastasis Surgical treatment was not attempted in four patients because of a poor general condition Thirty-one of the remaining 41 patients underwent complete removal of the tumor and 10 underwent incomplete removal or biopsy Myasthenia gravis was the cause of death of three of the five patients who died after operation There was no evidence of recurrence of the tumor in any of the patients whose tumor was removed completely The tumor itself was usually fatal in patients with ineradicable lesions Intensive roentgen therapy for ineradicable tumors seemed to benefit some patients Exploratory thoracotomy is indicated for all patients with mediastinal tumors whose general condition will permit, because there is no basis clinically or roentgenologically for the accurate pathological diagnosis of these tumors

Cavernostomy for Residual Cavity.—Murphy and Koontz performed cavernostomy on 23 patients with pulmonary tuberculosis and residual post-thoracoplasty cavities. Cavernostomy was carried out in two stages. Regenerated ribs and muscle bundles overlying the cavity were excised, the parietal pleura exposed and as large an extrapleural space as possible developed in the first stage. Ten to 14 days later, as large an area of the cavity as possible was unroofed by the electrocautery knife or, if the large vessels were threatened, by sharp dissection and a gauze pack placed into the cavity and left there for four days. It was then removed and the sinus packed daily with gauze moistened with an antiseptic solution. After a period varying from three to five months the drainage usually became thin and scanty. The sinus tract narrowed and epithelialized. Closure was attempted if three successive cultures of both the sputum and drainage material were negative and planigrams indicated eradication of the cavity. One gram of streptomycin in two divided doses, 0.5 Gm. each, was administered daily for one week preoperatively and two weeks postoperatively. Sixteen of the 23 patients had the resultant sinus tract closed by a muscle plastic operation, with streptomycin used as an adjunct. Closure was accomplished in 13 of these, who were followed for periods varying from one to two years. They had a negative sputum. Seven patients still have a draining sinus. Three of these were recent cases, in which closure will ultimately be effected. The remaining three were poorly selected cases in which closure could not be accomplished. The residual cavity was definitely eradicated, as revealed by planigraphic studies in 12 of the 16 patients whose sinuses were closed. Three of the remainder had planigraphic roentgenograms consistent with bronchiectasis in the former cavitary area. Two of these had a consistently negative sputum nearly two years after closure. One definite recurrence of sinus and cavity required lobectomy. Cavernostomy with streptomycin as an adjunct offers a satisfactory form of treatment for patients with residual cavities who are not suitable risks for resection.

The 1949 Poliomyelitis Epidemic. E. M. Cook Jr., T. Anton and E. S. Sherwood.—p. 337.

Familial Polyposis of Colon.—Clark and Parker report the occurrence of polyposis of colon in one family. The mother died of cancer of the colon at 41 years of age. No history concerning her siblings or parents was obtainable. She gave birth to 10 children, three having polyposis of the colon and one having died from cancer of the colon at 34 years of age. The three children of the latter, aged 17, 16 and 14, had polyposis of the colon. It is a disease characterized by a high incidence of malignant degeneration at an early age. The diagnosis is best established on the basis of a familial history and repeated, painstaking examination of the large bowel. The treatment is surgical extirpation of the entire large bowel. In adults treatment should be based on the presumption that malignant degeneration is imminent, making total colectomy necessary. Terminal ileostomy and removal of the colon to the lower sigmoid in one stage may often be feasible in a young patient who is a good operative risk. This may be followed by an abdominal perineal resection of the rectosigmoid. In rare instances where there is no disease in the rectosigmoid, preservation of this segment and anastomosis with the terminal ileum is practicable. The authors believe that, when the disease is sufficiently limited to the rectosigmoid, ileosigmoidostomy or ileoproctoscopy followed by fulguration of the polyps in the remaining rectosigmoid is not rational treatment. Polyps recur rapidly in areas that have been previously fulgurated and are frequently so numerous that fulguration is not practical. Malignant degeneration may occur and advance rapidly. The treatment of this disease in adolescence is fraught with hazards of nutritional deficiencies incident to an ileostomy. It may be possible to predict the age at which malignant degeneration will occur within wide limits on the basis of duration of the disease, the observed size and number of the polyps and the age at which malignant degeneration has occurred in antecedents or siblings. Careful observation and postponement of surgical treatment is justifiable if these factors indicate that malignant degeneration will not occur until after maturity.

Renal Tumors. H. Fisketti.—p. 799.

Methemoglobinemia Due to Nitrates.—According to Rosenfield and Huston, methemoglobinemia due to nitrates in well water is widespread in certain rural regions of the United States and Canada. In Minnesota 146 cases of methemoglobinemia from this cause, including 14 deaths, have been reported. Dry and evaporated milk formulas as well as diluted cow's milk formulas, which require large amounts of water as diluent, are most dangerous for infants. Since no infants who were breast-fed developed methemoglobinemia, this seems to be another argument in favor of breast feeding, especially in rural areas. Data are presented on water supplies suspected of being implicated in cases of infant methemoglobinemia in Minnesota. In all but two of these cases, the nitrate nitrogen content of the water was in excess of 20 parts per million. Periodic sampling over a one year period indicated that the nitrate concentration of a well remains fairly constant. Reconstruction of two wells failed to show, as some workers thought, that good well construction for a depth of 10 feet would exclude nitrates. Nitrates seem to occur more frequently in shallow wells (75 feet or less), than in deep wells. No method was found by which nitrates could be removed from water. None of the cases of methemoglobinemia in Minnesota occurred from the use of water containing less than 30 parts per million of nitrate nitrogen (NO_3N). However, 10 parts per million has been accepted as the point above which the water should be viewed with suspicion, because of the possibility of a dangerous level being reached through other factors such as boiling.

Subacute Bacterial Endocarditis.—Littmann and Schaaf compare therapeutic experiences in subacute bacterial endocarditis from 1947 to 1949 with those for the preceding three years. The adequately treated failures, numbering 23 cases, were separately compared with the 52 recoveries. Early recognition and adequate antibiotic therapy were important in obtaining cures and limiting permanent structural damage Most deaths (17 of 23) occurred as a consequence of irreversible cardiac, renal or cerebral changes, despite sterilization of the blood stream Infection was present terminally in only six cases, and four of these were considered to be due to truly resistant organisms The nutritional state of the patients was found to be of prognostic value In approximately half the failures the patients were poorly nourished, and only 6 per cent of the cured patients were so designated Uremia and congestive failure were ominous events during the course of subacute bacterial endocarditis and commonly foreshadowed an unsuccessful termination Patients with the most serious heart disease fared the least well There was a relatively high incidence of congenitally bicuspid aortic valves in those who died Although more resistant to therapy, subacute bacterial endocarditis was found to be less frequent (by almost 50 per cent) in recent than in former years The reduction in total numbers was thought to be due in part to the currently widespread and probably justified use of antibiotics in patients with valvular heart disease for diagnoses other than bacterial endocarditis

Thrombopenic Purpura—A clinical syndrome characterized by fever, a rapidly progressing anemia mild icterus, thrombopenia, central nervous system manifestations and death in a relatively short time was first described by Moschcowitz in 1925 Since that time a limited number of cases that seemed to fit this picture clinically and pathologically have appeared in the literature The outstanding features at necropsy were numerous petechial hemorrhages of the heart, kidneys liver and brain, which microscopic examination revealed to be due to platelet thrombi As yet, this peculiar sequence of events has not been explained but in all likelihood it is initiated by a spontaneous deposition of the blood platelets, owing either to an upset in the coagulating mechanism of the blood or to a preceding capillary and arteriolar injury The authors describe the case of a young woman, aged 23, who had this type of disorder and in whom psychiatric manifestations were so prominent that she was at first believed to have a major psychosis and was placed in a mental institution No effective treatment has so far been found for this disease

Streptomycin for Childhood Tularemia—According to Levy and his associates, 48 children with tularemia were treated at the Charity Hospital of Shreveport, La, during the period May 1943 through July 1949 Twenty-four children were treated with streptomycin The average total dose administered to a patient was 8 37 Gm, given for an average duration of 7 46 days, later dosage averaged 1 Gm daily for five to six days (125 mg at three hour intervals) This is in excess of the dose recommended by Foshay, who suggests 0 5 Gm daily for two days followed by 0 25 Gm daily for four days or, as an alternative course, 0 5 Gm daily for six days There were no instances of toxicity or sensitivity, despite the relatively large doses used at first, with the lower dose and shorter course now advocated, this danger will be lessened even more The rapid response to streptomycin observed in every child in this series proves the efficacy of this antibiotic against Pasteurella tularense Since the diagnosis of tularemia in childhood may be extremely difficult, especially in those cases in which an adequate history is lacking, there is justification for inclusion of a therapeutic trial with streptomycin for every severely ill child who fails to respond to other treatment

Vitamin B_{12} in Seborrheic Dermatitis.—Andrews and his associates used vitamin B_{12} in treatment of 101 patients with dermatological disorders They were prompted to use this preparation because of the beneficial effects obtained with crude liver extract and vitamin B complex in metabolic and nutritional deficiency states While many patients with seborrheic dermatitis have a mild, usually normocytic or hypochromic anemia, the response of the skin disease could not be judged from the red blood cell count, hemoglobin, hematocrit studies or reticulocyte count The vitamin was administered by intramuscular injection Local treatment was not neglected Patients with secondary infections of the seborrheic areas were treated with sulfonamides and penicillin Improvement usually manifests itself after two or three injections Many of these patients have no recurrences A mild recurrence usually can be treated satisfactorily with a few additional vitamin B_{12} injections, and recurrences have been prevented entirely by a maintenance dose of 15 or 30 micrograms of the vitamin given intramuscularly every two or three weeks Where other metabolic, endocrine and nutritional factors are implicated and appropriately treated recurrences will not appear Of 37 patients with seborrheic dermatitis who were studied thoroughly, 16 were cured, 16 improved, 3 only slightly improved and 2 were worse The authors conclude that these results are superior to those that can be obtained by local treatment alone They believe that this is essentially a nutritional disease Pityrosporum ovale, other cryptococci, staphylococci and streptococci are probably saprophytes or secondary invaders They account for many of the inflammatory features of the disease

Pulmonary Calcification in Students—This study by Prior and his associates is based on the records of 4 829 students who entered Ohio State University in the fall of 1946 and 1948 Preliminary histoplasmin and tuberculin skin tests were required, and a satisfactory roentgenogram of the chest taken at the time of admission had to be available The group was further limited to lifetime residents of a given county The distribution of cases of pulmonary calcification in Ohio followed a definite geographic pattern which closely parallels the geographic distribution of histoplasmin reactors but does not correspond to the distribution of tuberculin reactors The incidence of tuberculin reactors tends to be higher in the metropolitan areas and lower in rural sections The incidence of both pulmonary calcification and histoplasmin reactors tends to be higher in the rural sections than in urban areas and also shows a definite geographic pattern Although many cases of calcification are undoubtedly due to tuberculosis, these facts indicate that most pulmonary calcification in Ohio and other Middle Western States is probably the result of a benign, widespread form of histoplasmosis or an antigenically related agent or agents

Relapse After Sulfone Therapy in Leprosy.—Erickson reports the recent discovery at Carville of the reactivation of leprosy in six patients in whom it was supposedly arrested by sulfone treatment Three of these cases, in which there was reappearance of leprosy bacilli in the skin without other manifestations, were classed as subclinical relapses In the remainder, there were, in addition, unquestionable leprous skin lesions or a true clinical relapse The disease was arrested by sulfone drugs in 77 patients who had active disease when treatment was begun Only 33 of these patients were kept under observation with routine clinical and laboratory examinations All had the lepromatous type of leprosy The duration of follow-up varied from six months to five years Among the 33 patients followed, 22 received glucosulfone sodium or sulfoxone sodium in smaller doses, either continuously or interruptedly after arrest of the disease Eleven patients received no antileprotic remedy after the disease became inactive Six relapses occurred among the 33 patients True clinical relapses, of which there were three, occurred only in the group that received no treatment after arrest of the disease These relapses occurred two to three years after the arrest Subclinical relapses occurred in both groups, two in the group not treated after arrest and one in the group treated The latter patient, however, had received a relatively small amount of sulfoxone sodium before the lesion became arrested The incidence of relapse seems to be lower if sulfone treatments are continued after inactivation of the leprosy

Treatment of Tuberculous Psoas Abscess—According to Hoover, the tuberculous abscess is one of the serious complications of tuberculosis of the spine This article concerns the treatment of the psoas abscess, which results from the burrowing of the detritus along the fascia of the iliopsoas muscle Because of its superficial manifestation, this abscess often requires differentiation from the various retroperitoneal abscesses and the iliac fossae abscesses of pyogenic origin Another problem arising from the tendency of the psoas abscess to become superficial is pressure necrosis of the skin, which may lead to a spontaneous rupture and mixed infection Aspiration of the abscess with a small needle was the method of choice before the introduction of streptomycin Surgical incision was feared because of the danger of a mixed infection and of the resultant draining sinus tract Psoas abscesses usually point in Petit's triangle, in the groin or in the thigh region The incision should be made with strict aseptic technic in a sound area of skin a suitable distance from the "pointing spot" The contents are removed, the cavity is flushed with isotonic sodium chloride solution, and streptomycin solution is instilled Streptomycin may also be given intramuscularly, but when this is done, sufficient levels may not be reached in the abscess cavity because of the poor blood supply of the tuberculous tissue The author describes several methods of surgical drainage and local use of streptomycin in the psoas cavity The instillation of streptomycin solution into the cavity, followed by closure in layers of the incision, was the method used at Johns Hopkins Hospital The immediate results were dramatic when surgical drainage was used in conjunction with streptomycin applied locally

Respiratory Studies in Paralytic Poliomyelitis.—The observations reported by Bourdillon and his associates were made during the 1949 epidemic of poliomyelitis. Numerous measurements of tidal air were made with a spirometer on patients and on healthy subjects in Both and Drinker respirators and on patients after respirator treatment for poliomyelitis. Among the subjects studied were nine patients for whom respirator treatment was considered essential. Five of these were too ill for experimental tests and died without having had any measurements of tidal air. The authors give data on the four surviving respirator patients and of the healthy subjects. The measurements showed a wide range of variation from day to day in most cases. The authors believe that in the treatment of poliomyelitis with respiratory involvement there is need for measurements of vital capacity and tidal air, unless frequent measurement of blood oxygen and carbon dioxide are practicable. Early measurements of vital capacity are suggested in order to detect the first signs of respiratory involvement, with a view to resting the muscles concerned by prompt use of a respirator. The tidal air measurements are indicated as a rough guide to the correct setting of respirator pressures, to avoid underventilation or overventilation. The potential dangers of hyperventilation are discussed, and measurements are given showing the ease with which they are obtained in respirators. The authors describe tests on the use of the prone position in respirators and stress the importance of using this position, especially in bulbar cases. They suggest improvements in the Both respirator, such as provision for slower speeds and reduction in the angle of slope and in the thickness of the front panel.

Complement Fixation Test for Herpes Simplex.—According to Dudgeon the serologic diagnosis of virus infections depends for the most part on neutralization and complement fixation tests. Both have been described in herpes simplex infections. The neutralization test is used almost exclusively at present, owing to the conflicting results obtained by the complement fixation. The author attempted to prepare a more satisfactory antigen from the developing chick embryo, as was done with other viruses. He reports on a preparation of a chorioallantoic membrane antigen and its use in the diagnosis of herpes simplex infections. Antigens prepared from the chick embryo have several advantages over antigens prepared from animal and, in particular, brain tissue. They are easy to prepare, they have a high virus content and are bacteriologically sterile and the risk of nonspecific results is reduced. At the same time control antigens from uninfected tissue are easily prepared. The chorioallantoic membrane was used in one case as the source of antigen in preference to the amniotic and allantoic fluids, which, although they showed positive fixation, were seldom as constant in titer and on occasions were anticomplementary. The interpretation of any complement fixation reaction depends to a great extent on the specificity of the reaction. The more sensitive and the more specific the test can be made, the greater is its value. This quality of specificity is largely dependent on the antigen itself. In the present investigation nonspecific results were almost entirely eliminated by (1) the use of the chorioallantoic membrane antigen, (2) the preparation of hyperimmune serums with homologous tissue and (3) inactivation of the serums at 62 C. for 15 minutes. The test appeared to be of value as an alternative diagnostic method in herpes simplex infections, in particular when a large number of serums have to be examined. It may also be useful in following the course of antibody production in cases of recurrent herpes infections.

Studies on Sensory Epithelium of Labyrinthine Crista Ampullaris in Fishes. T. Vilstrup.—p. 420.

Rubella Congenital Inner Ear Deafness.—Hiller reviews the results of examination of 42 children with congenital inner ear deafness, the mothers of some of whom had had rubella during the Australian rubella epidemics of 1937-1940. The children have now reached the age at which they are able to offer full cooperation for examination of their hearing.

The deafness in 32 cases was due to rubella occurring in the mother in the early months of pregnancy; the other 10 are classed as nonrubella inner ear deafness cases. The degrees of deafness and the types of audiometric curves of various groups of children were analyzed. The average degree of deafness in the rubella-deaf group is less than that in the nonrubella cases. The audiograms of the rubella-deaf subjects show a great diversity of patterns. In general, low tones are less affected than high tones, but any downward trend in the curve of the audiogram is less steep than in typical inner ear deafness. The incidence and severity of rubella deafness and also the incidence of accompanying rubella retinitis appear to be directly dependent on the severity of the maternal rubella infection. Analysis of supposed nonrubella deafness made the authors believe that some of these cases may have resulted from maternal infection with rubella during early pregnancy. They also suggest that cases of congenital inner ear deafness with typical audiometric curves are probably hereditary in origin, while those with atypical graphs may be the result of antenatal infection, such as rubella, in the mother.

Vitamin C Deficiency in the Tropics.—According to Stransky and his associates nutritional problems are becoming more important in the tropics because millions of persons are going to the cities and are shifting from agriculture to mining, industry, commerce and clerical work. People living in large centers of population in the tropics have no means for preservation of food; hence a diet consisting mostly of nonperishable foods must be adopted. While in rural districts there is frequently plenty of fresh food, such as fruit and vegetables, the city dwellers live mostly on carbohydrate-rich food. Infants are exclusively breast fed or are given only diluted condensed milk, since condensed milk can be kept without refrigeration. Fresh vegetables and fruits are not given to infants, even in the second year of life. The authors determined the vitamin C (ascorbic acid) content in 20 samples of human milk, in the blood plasma of 89 nursing mothers and in the blood plasma of 124 children, 32 of them infants below the age of 1 year. Ninety per cent of all examined samples revealed levels below normal and 60 per cent far below normal, while 30 per cent showed levels suggestive of scurvy. The authors conclude that ascorbic acid deficiency is a public health problem of paramount importance in the tropics.

Indications for and Prognosis in Surgical Treatment of Gastric and Duodenal Ulcers. W. R. S. Hutchinson.—p. 203.
*Modern Trends in Spinal Anaesthesia. A. R. Hunter.—p. 206.

Modern Trends in Spinal Anesthesia.—Hunter feels that it is now possible to make a much truer assessment of spinal anesthesia. He reviews the physical factors, the physiological and circulatory factors, the neurophysiological aspects and the nervous complications. Limits to the use of spinal anesthesia are set by the competence of the anesthetist, the physical state of the patient and the type of operation to be performed. In the hands of the inexperienced, both inadvertent overdosage and partial failure will be common. When the method is used by the unintelligent, who believe that the dose is "the contents of one ampule," frequent catastrophes are inevitable. Contraindications to spinal anesthesia are local or general sepsis and disease of the spinal cord. The most serious contraindication is cardiovascular insufficiency of such a degree that the patient is unable to compensate for the vasodilatation which is produced. Patients with serious blood volume deficiency come into this group, even if the blood pressure is maintained at normal levels by compensatory vasoconstriction. So also do those with severe myocardial failure. The patient's temperament is not a guide to his suitability for spinal anesthesia. With adequate premedication the most nervous patient can be given a spinal anesthetic. Spinal anesthesia is unsuitable for operations above the xiphisternum, nor is it likely to give satisfactory results when used alone for operations in the upper part of the abdomen, since in this region the segmental level of the autonomic innervation of the viscera is so high that complete vasomotor paralysis is an almost inevitable accompaniment of adequate spinal block. For operations on the colon, on the small bowel, for suprapubic exploration of the bladder and for all operations deep in the pelvis, spinal anesthesia provides an unvarying degree of relaxation and an immobility of the viscera that is not obtainable with any other anesthetic technic.

*Gravitational Leg Syndromes. W. Girdwood.—p. 114.

Gravitational Leg Syndromes.—Girdwood points out that, although much discomfort, ill health and restriction of normal activities are caused by chronic varicose ulcers, varicose veins and postphlebitic lesions, little permanent success has resulted from the treatment usually employed. The temporary nature of the relief afforded has been due to the failure to appreciate the magnitude of the problem involved. Gravitational leg syndromes are an assortment of disorders in which a series of vicious cycles occur, constantly aggravating the condition and leading to a final picture involving venous antigravity failure, failure of the "pump" and a chronic, indurated leg ulcer with scarring. Three links should receive attention in the cycles which predominate: the ulcer, the pump and the veins. In the strip grafting which the author recommends the indurated scarred tissue about the ulcer and the ulcer itself are excised. It is important to preserve a healthy layer of covering to the tendons, which is usually possible. A long incision is made extending above the ulcer to the upper part of the leg and often another below the ulcer. The deep fascia is incised in the line of the incision or excised, and the underlying muscle is exposed. If the communicating veins are incompetent, these are divided. If there is foot drop, lengthening is done at this stage at the level of muscular fibers. A split skin graft, usually in one piece, is then applied to this raw area. The three irreversible factors, scar, lymphedema and skin stricture, are overcome by this procedure. The graft, placed on a healthy base, obtains its nutrition from the deep tissues through the muscle; because of the continuity of the graft on muscle with the graft over the previous ulcer site, the nutrition continues to that area and even to the neighboring skin. Skin stricture is relieved by strip grafting as the graft acts as a "let in" procedure, thus overcoming the stricture. The operation results in firm support to the communicating veins and allows the correction of antigravity failure of the communicating veins. Shortening of the Achilles tendon is corrected, and ankle movements are restored. Strip grafting attacks not only the ulcer problem but the vein problem, and by mobilization of the ankle and removal of pain it reconstitutes the pump.

*Tracheobronchial Tuberculosis and Streptomycin. W. Mascher and S.-B. Mattson.—p. 114.

Tuberculin Sensitivity in Boeck's Sarcoid.—Bjørnstad used up to 10 mg. doses of tuberculin in intracutaneous tests of 71 patients with Boeck's sarcoid and with definite skin lesions. Fifty patients (70.4 per cent) had a negative reaction and 21 (29.6 per cent) a positive reaction. Twelve patients had a positive reaction to 0.1 mg.; two had a positive reaction to 0.01 mg., but none had a positive reaction to smaller doses. The tuberculin sensitivity of the tuberculin-positive patients with Boeck's sarcoid is weak. Fifty of the patients were aged over 40; 33 had a negative reaction to tuberculin. Nine of the 50 patients with a negative reaction had been exposed to tuberculosis in their homes. The chest roentgenograms of 11 of these 50 patients showed calcium shadows, which most likely indicated a previous tuberculous infection. The frequency of the negative reactions must be due to Boeck's sarcoid itself and cannot be due to the fact that the patients with a negative reaction have escaped tuberculous infection. It is possible that a large number of patients with sarcoid had a negative reaction to tuberculin because their tuberculous infection had been cured. Negative intracutaneous tests with up to 1 mg. of tuberculin will afford valuable aid in differentiation of Boeck's sarcoid and tuberculosis. The diagnostic significance of negative or weak reactions to tuberculin is greatest in patients with skin lesions or involvement of lymph nodes, while negative reactions are of lesser diagnostic significance in patients with pulmonary involvement resembling miliary tuberculosis. From the etiological point of view the absent or weak tuberculin sensitivity is due to a hitherto unknown chronic infection which causes increased resistance to tuberculosis. The tuberculin anergy and resistance to tuberculosis in Boeck's sarcoid may or may not have a purely tuberculous etiology.

Streptomycin in Tracheobronchial Tuberculosis.—Mascher and Mattson treated 22 patients with tracheobronchial tuberculosis with streptomycin. The drug was administered by aerosol, 0.5 Gm. dissolved in 10 cc. of isotonic solution of sodium chloride daily, and by intramuscular route, 1 Gm. in two divided doses of 0.5 Gm. daily. Five patients were given aerosol treatment alone; nine received the drug by intramuscular route alone; two were treated simultaneously by aerosol and by intramuscular injection, and six were given alternating aerosol and injections. Bronchoscopic examination showed that healing of the local process occurred in 17 patients, five of whom were treated by aerosol alone, eight by injections alone, one by aerosol and injection simultaneously and three alternately by aerosol and by injection. Three patients were improved, and treatment failed in two. Nine patients had become free from Koch's bacilli. Results of bacterial tests were positive in eight patients whose local process was healed, but six of them had active pulmonary lesions which accounted for the presence of bacteria. Relapse occurred in three patients. Three patients had vestibular symptoms, but treatment had to be discontinued in only one. Two patients had allergic symptoms. Desensitization was achieved in one with 0.01 Gm. of streptomycin given twice daily for eight days and doses increased gradually to 0.02, 0.03, 0.05, 0.1 and 0.25 Gm. twice daily. Fibrotic stenosis developed in five. Treatment for four to six weeks with a total dose of 50 to 60 Gm. should be sufficient for mild lesions of mucous membranes; the authors caution against too early discontinuance of treatment, because of threatened relapses. Combined treatment by aerosol and by intramuscular route is recommended because greatest concentration of the drug in the affected tissues, i. e., in the bronchial wall, may thus be achieved. Endobronchial tuberculosis should be treated with streptomycin before collapse therapy is considered.

*Should the Right Ventricle Be Punctured During Venous Air Embolism? S. Frey—p. 305.

Right Ventricle Puncture During Venous Air Embolism.—Frey says that, although ventricular puncture had been largely given up as treatment for venous air embolism, two recent reports about the alledgedly successful treatment of air embolism by ventricular puncture call for reinvestigation. He cites animal experiments which indicate that air is found in the right side of the heart when large quantities of air have been injected intravenously, not because of failure of the heart as the result of air filling, but because the pulmonary vessels are blocked by a part of the air and the escape of the remainder of the air is mechanically prevented. The author explains death as the result of venous air embolism in the following manner. Air which reaches the right side of the heart through a vein is driven in the form of bubbles into the pulmonary artery. These bubbles remain in the branches of the pulmonary artery. If complete blockage of the pulmonary circulation is produced by the air bubbles, death results, because the organism receives no oxygen (asphyxiation). Blockage of a large part of the lung (about two thirds) likewise causes asphyxiation, but if blockage of the circulation is such that an adequate amount of blood can still be oxygenated, then mechanical impairment of the heart action by the blockage in the pulmonary circulation may result in death (heart death). The clinical course of air embolism depends not so much on the quantity of air but on the rapidity with which it enters the circulation. Enormous quantities of air can be injected into animals without unfavorable effects, provided the injection is made slowly, because then the air enters the right heart in small bubbles and is driven into the small ramifications of the pulmonary artery, so that only small parts of the lung become blocked. If the air enters rapidly and large bubbles enter the heart, these large bubbles block the large branches of the pulmonary artery and completely interrupt the pulmonary circulation. This explains also why entrance of air into veins close to the heart leads to rapid death, whereas air in peripheral veins is comparatively harmless. In some cases air embolism causes no clinical symptoms, in other cases symptoms such as dyspnea, palpitation, piercing pains in the chest, anginal pains and vertigo rapidly disappear. In fatal air embolism death may be sudden or protracted. The breathing of oxygen and the intracardiac injection of epinephrine are the most effective methods in air embolism. The aspiration of air from the right side of the heart by means of percutaneous puncture is not advisable, because it is based on a mistaken assumption. The author analyzes the aforementioned two cases and questions the life-saving effect of cardiac puncture.

*Testosterone in Treatment of Incurable Carcinoma of Female Genitalia. H. Burger and H. Drescher.—p. 835.

Immunity After Typhus.—According to von Bormann, of 259 inhabitants of a Russian village who had had typhus 10 or 20 years previously, 66 (about a fourth) contracted typhus a second time. Only 11 of these second attacks had an abortive course; 15 were severe. There were no fatalities. In the adult inhabitants who did not have typhus previously, the morbidity was 52 per cent. The author concludes from this that, although an attack of typhus confers protection, it does not confer lifelong immunity.

Testosterone for Incurable Carcinoma of Female Genitalia.—Burger and Drescher state that 20 women with incurable carcinoma of the genitalia were treated with testosterone propionate at Women's Clinic of the University of Tübingen. Irradiation was usually continued during the time the male hormone preparation was given. Some patients were given, in addition, so-called mitosis toxins, such as arsenic, nitrogen mustards, colchicine or choline. Improvement was observed in 13 patients who were treated with doses of 100 to 400 mg. of testosterone propionate. The general condition improved, pain subsided, the appetite improved and some showed an increase in weight and a decrease in menopausal symptoms. Although the fatal outcome could not be prevented, life was prolonged in some instances. The hormone treatment failed in two cases.

Sugar Values of Normal Cerebrospinal Fluid During Fractional Withdrawal. H. Weise.—p. 416.

Pancreatic Glucagon.—Gaede and his co-workers direct attention to the so-called paradoxical effect of insulin, which consists in a mild increase in blood sugar immediately before the hypoglycemic effect of insulin becomes manifest. A substance which is glycogenolytic and increases blood sugar has been isolated as the result of careful chemical preparation of pancreas from horses and of substances remaining after the extraction of insulin from cattle and swine pancreas. This pancreatic substance, which has been designated a glucagon, is a pancreatic hormone. The pancreas contains three systems. The excretory system produces digestive enzymes as well as lipotropic substances, which Dragstedt designated a "lipocaic" and which is probably identical with what Gavin, Patterson and McHenry termed inosit. The beta cells of the pancreas produce insulin. To determine what part of the pancreas produces glucagon, the antagonist of insulin, which increases blood sugar, the exocrinic portion of the pancreas was destroyed in a dog by ligation of the excretory ducts. Subsequently, the beta cells were destroyed in this animal by the injection of alloxan. This turned the pancreas into a connective tissue body which, besides small remnants of atrophic lobules, contained only alpha cells. Extracts of this gland had only the effect of increasing the blood pressure. It appears, therefore, that the increasing blood pressure factor glucagon, originates in the alpha cells. The role of these cells and the insulin-producing beta cells in the regulation of the carbohydrate metabolism is discussed. Insulin reduces the blood sugar content and promotes the synthesis of glycogen; glucagon, on the contrary, increases the blood sugar and promotes the decomposition of glycogen. Glucagon produces glucose, and insulin further oxidizes it. This probably explains why both hormones have an antiketogenic effect. The alpha cell system probably plays a role in the reaction of the organism to insulin and might cause, or at least influence, the tendency to acidosis observed in some diabetic patients. It is probable that glucagon is responsible for the distinctive characteristics of certain forms of diabetes.

*Site of Formation of Renin in Kidneys. A. C. Taquini, J. C. Fasciolo and D. Fernández Luna.—p. 174.
*Diabetes Mellitus in Infant Five Months Old. J. C. Recalde Cuestas, J. J. Staffieri and P. O. Tommasino.—p. 185.

Place of Formation of Renin in Kidneys.—Taquini and collaborators made quantitative determinations of renin in the kidneys of dogs, cats and pigs. They used a method which permits measurement of this substance in minute quantities in renal tissue. They found that renin is either produced or stored in the convoluted tubules in the outer layer of the renal cortex. The results did not indicate whether the proximal or the distal segments of the convoluted tubules play the predominant role in the formation or storage of renin.

Diabetes Mellitus in Infant.—Staffieri and Tommasino report diabetes mellitus in a five month old infant; they believe this to be the first in the Argentine medical literature. There was neither obesity nor diabetes in the family. The infant did not have any infectious process before the appearance of diabetes. The diet had to be approximated as far as possible to a normal diet suitable for a patient of this age. The disease caused acute toxic symptoms. The liver was enlarged. The treatment consisted of 5 units of insulin given every four hours. The daily maintenance dose of insulin was reduced to 8 units, given in two doses of 4 units each.

*Aureomycin and Chloramphenicol in the Treatment of Whooping Cough. L. Barbera and G. Marchese.—p. 177.
*Combined Penicillin and Synthetic Antihistamine in Treatment of Glomerulonephritis in Children. V. Baffi.—p. 198.

Aureomycin and Chloramphenicol in Whooping Cough.—Barbera and Marchese treated 18 children with whooping cough with aureomycin and chloramphenicol. A dose of 50 mg. a day of either drug per kiligram of body weight was administered four times in 24 hours for five to eight days. There was a definite improvement in every case as evidenced by the lessening of the number and intensity of paroxysms, rapid recovery of the general health and return of sleep and appetite. The earlier treatment was started, the more pronounced these results. Suckling infants benefited most from the treatment. With the exception of a mild intolerance toward aureomycin in some of the youngest children there was no difference in the therapeutic effect of the two drugs.

Combined Penicillin and Antihistamine in Glomerulonephritis in Children.—Baffi reports five cases of glomerulonephritis in children between the ages of 2 and 10 years. The disease in all cases was due to a pharyngeotonsillar infection. The combined treatment consisted of administration of penicillin and of antihistaminic drugs. Penicillin was given by the intramuscular route every three hours in a daily dose of 160,000 units for 10 to 20 consecutive days. The antihistaminic drug was given in daily doses of four or five tablets of 0.10 Gm. each in the course of penicillin treatment and for five days more after discontinuation of penicillin. The disease was controlled in the first week of treatment. The author concludes that the combined treatment gives better results than either penicillin or antihistaminic drugs alone.

*Clinical Aspects and Problems of Polyradiculitis in Childhood (Guillain-Barré Syndrome). E. Glanzmann.—p. 622.

Clinical Picture and Problems of Guillain-Barré Syndrome.—Glanzmann reports nine cases of Guillain-Barré syndrome in children. The syndrome occurred as an idiopathic disease in a girl aged 4; it was associated with encephalomyelitis after measles in a girl aged 7, and with Landry's paralysis in a girl aged 2. One girl aged 11, who had had poliomyelitis at the age of 7, had Landry's paralysis with a complete recovery. It seems likely that her first as well as her second disease was a Guillain-Barré syndrome, since allergic reactions have a tendency to recur. Two brothers aged 1 and 4 years had erythredema polyneuropathy associated with Guillain-Barré syndrome. One girl aged 4 had erythredema polyneuropathy and polyradiculitis, which presented itself as a febrile, intercurrent, secondary infection. Radiculitis with great increase in the protein in the cerebrospinal fluid, without a corresponding increase in cells, occurred, during an epidemic of poliomyelitis, in a boy aged 4 after severe gastroenteritis. One boy aged 6 with megasigmoid had amyotrophic polyneuritis associated with Guillain-Barré syndrome which was probably due to a deficiency of vitamin B_1 caused by an abnormal bacterial condition in the intestine. The epidemic occurrence of polyradiculitis with or without simultaneous epidemic of poliomyelitis, the occurrence of polyradiculitis in siblings and the sporadic occurrence of polyradiculitis independent of any other disease suggests that a specific neurotropic virus may possibly be the causative agent. Polyradiculitis could be considered as a sister disease of poliomyelitis, the relation being similar to that of parapertussis and true pertussis. Polyradiculitis can be differentiated from poliomyelitis by the clinical picture.

*Hemolytic Disease in Newborn Due Only to ABO Incompatibility, Successfully Treated with Transfusion of O-Erythrocytes and AB-Plasma. R. Seigneurin, J. Roget, J. Groulade and F. Viallat.—p. 939.

Hemolytic Disease in Newborn Due only to ABO Incompatibility.—Seigneurin and co-workers report an infant boy born at term, his parents' second child, with icterus occurring several hours after birth and becoming severe within the succeeding 24 hours. The Rh factor was not responsible for the icterus, since the father was B Rh positive, the mother O Rh positive and the infant B Rh positive. Determination of the ratio of the regular agglutinins in the mother's serum showed an abnormal increase in anti-B agglutinins (1:2048). Erythroblastosis and leukocytosis in the infant resulted from maternal isoimmunization to hemoagglutinogen B. This also caused the passing of anti-B antibodies into the milk of the mother in the same high ratio as in the mother's serum. The infant was given three transfusions of 100 cc. of blood into a fontanel. The first transfusion was given 38 hours after birth, the second 18 hours later and the third on the twelfth day of life. The transfused blood was artificially composed of O erythrocytes in suspension in AB plasma. The mother's milk was withheld from the infant. The icterus became less severe on the third day and disappeared completely on the ninth day. Erythroblastosis and leukocytosis subsided, and the number of red blood corpuscles increased. The infant was apparently cured when it was discharged from the hospital on the twentieth day.

*Surgical Treatment of Pulmonary Tuberculosis: Upper Partial Thoracoplasty. Based on Results in 577 Thoracoplasties. E. J. Zerbini and M. Alves Lima.—p. 489.

Surgical Treatment of Pulmonary Tuberculosis.—Zerbini and Alves Lima performed 577 partial thoracoplasties in 333 patients with pulmonary tuberculosis. The disease was unilateral in 150 cases and bilateral in 183. The contralateral lesion in the latter group was controlled after (unilateral) thoracoplasty by pneumothorax in 87 patients, by pneumothorax and Jacobaeus' operation in 15, by pneumothorax with crushing of the phrenic nerve in five, by extrapleural pneumothorax in two and by bilateral thoracoplasty in three; the contralateral lesion healed spontaneously in 71 patients. The cavity in these patients had a diameter of less than 3 cm. in 83, of more than 3 cm. in 193 and of more than 8 cm. in 57. Thoracoplasty was performed in only one stage in 111 patients, in two stages in 197, in three stages in 10, in four stages in three. Upper partial thoracoplasty resulted in cure in 174 patients (52.5 per cent) between one and 13 years after the operation. The operation is likely to fail because of the coexistence of pulmonary and bronchial tuberculosis. A roentgenologic and bronchoscopic diagnosis of bronchial tuberculosis is important. Treatment of the pulmonary lesion, when both types are present consists of a cavernoscopy, when the general condition of the patient is poor, and of lobectomy or pneumonectomy, if the general condition of the patient makes the operation advisable.

*Myocardosis Associated with Cirrhosis of Liver. M. Oppenheim.—p. 795.

Angiocardiopneumography in Diagnosis of Tumors of Lung and Mediastinum. M. Battezzati, F. Soave and A. Tagliaferro.—p. 799.

Myocardosis Associated with Cirrhosis of Liver.—Oppenheim reports cirrhosis of the liver in 128 men and 40 women. Seventy-eight of the patients (57 men and 21 women) died, and necropsy was performed. Signs of myocardosis were observed in a considerable number of the living patients and in all the fatal cases. Pathological conditions of the blood proteins were observed in practically all. A positive Weltmann reaction, increased sedimentation rate of blood, positive cadmium reaction, lowering of total protein ratio and increase of alkaline phosphatase were the most frequent and constant pathological signs in the living patients and in the fatal cases, but these signs were more frequent and more pronounced in the fatal cases. Definite correlation was observed between the severity of the anatomic disease, the disturbance of the protein chemistry, the pathological electrocardiograms and the course of the disease. There were twice as many patients without hypoproteinemia who survived as there were patients without hypoproteninemia who died, while the number of patients with hyproteinemia who survived equaled the number that died. Fatal cases were less frequent among patients with normal electrocardiograms. Hypoproteinemia proved to be first and the pathological electrocardiogram second with respect to prognostic significance. There exists a reciprocal effect between dysproteinemia, particularly hypoproteinemia, and myocardosis, in that the hypoproteinemia contributes considerably to the development of myocardosis. Since hepatic lesions are manifested by dysproteinemia, the myocardosis associated with cirrhosis of the liver should be considered a hepatogenic disease of metabolism of the myocardium.

*Nephro-Omentopexy: Therapeutic Results. J. C. Rudler and J. Cottet. —p. 2915.

Observations Concerning Bronchoscopic Topography and Catheterization of Bronchial Orifices. G. Arnaud and J. Ioannou.—p. 2923.

Capillary Hyperpermeability: Treatment in Post-Traumatic Local Reflex Syndromes. H. Laborit.—p. 2930.

Nephro-Omentopexy. — Rudler and Cottet performed nephro-omentopexy on 13 patients, 12 of whom had typical nephroangiosclerosis with retention of urine and albuminuria; one had acute nephritis in the phase of transition to chronic nephritis with hypertension. Ten of the 12 patients with nephroangiosclerosis were hypertensive. Urinalysis and renal function tests were done before the surgical intervention. Thus a definite functional difference was frequently revealed in the two kidneys. Surgical intervention was performed on the kidney whose function was impaired to a greater extent. Catheterization of the kidneys was repeated three to six months after intervention. The function of the kidney operated on was equal or superior to that of the other kidney. Two patients died of anuria within the first six postoperative days. Five additional patients died within three months to two and a half years after operation, three of them from cardiac failure. Two more patients died within three years and three months after the operation. Two of the four surviving patients were subjected to bilateral nephro-omentopexy. The preoperative blood urea levels of 1.05 Gm. and 1 Gm., were reduced to about 0.50 Gm. in these two patients. The phenolsulfonphthalein excretion was reduced to 25 per cent in the first of these patients, and fatigability, headache and digestive disturbances were improved in the second patient. Cardiac decompensation and blood urea above 1.80 to 2 Gm. are definite contraindications of nephro-omentopexy. One should perform renal function tests and catheterization in order to avoid surgical intervention in a phase of an ascending uremic bout and also to prevent the risk of operating on the only kidney which may still have some of its function while the other is no longer functioning. Nephro-omentopexy did not aggravate the renal function in any of the authors' cases, although all of them were severe. Ureteral catheterization showed that the kidney operated on was improved as compared to that not operated on. It seems necessary that both kidneys be operated on. Although nephro-omentopexy is not the ideal treatment for chronic nephroangiosclerosis, it may induce improvement in patients whose condition is not so severe. Arterial hypertension and albuminuria are not benefited by nephro-omentopexy.

*Effect of ACTH and Cortisone in Rheumatic Fever. A. Videback, G. Asboe-Hansen, P. Astrup and others.—p. 919.
Importance of Cultivation of Gonococci from Rectum in Women. K. Bülow.—p. 929.

ACTH and Cortisone in Rheumatic Fever.—Videback and his associates report that treatment with pituitary adrenocorticotropic hormone (ACTH) gave remarkably good clinical results in a girl, aged 15, with a first acute attack of rheumatic fever and in a woman, aged 28, with fever and joint disorder of almost a year's duration. It had more doubtful effect in a youth, aged 16, who also had a first acute attack of rheumatic fever and in whom earlier treatment with cortisone was without noteworthy result. Temperature and pulse rate improved strikingly in all patients. The general condition was noticeably better. The pronounced exudative pericarditis in the first patient decreased rapidly during and after treatment; in the second patient, with pancarditis, there was some decrease in the heart shadow; in the third patient, with pericarditis, the heart shadow was not affected. In all patients there were moderate amounts of hyaluronic acid in the connective tissue before treatment, but none was demonstrable in the skin when the treatment was terminated. Reduced healing power in wounds was noted in one instance. Complicating infections developed in two patients.

*Mortality and Danger of Cancer of Stomach in Patients with Pernicious Anemia. J. Mosbech and A. Videback.—p. 985.
Two Cases of Secondary Intestinal Tuberculosis Treated with Para-aminosalicylic Acid. O. Jensen.—p. 991.

Cancer of Stomach in Patients with Pernicious Anemia.—Mosbech and Videback say that of the 301 patients with pernicious anemia (219 women, 82 men) treated in Bispebjerg Hospital from 1928 to 1949, 224 were observed for more than 10 years. Follow-up of these cases showed that life expectancy for women who were treated for pernicious anemia is the same as that of the normal population and that for men there is a slightly but not significantly higher mortality. Of the total number of patients, 115 (83 women, 32 men) were dead. Twenty-one patients died from cancer, which corresponds to the expected number of deaths from this disease, but no less than eight women and seven men had cancer of the stomach. The higher incidence of cancer of the stomach in the men is difficult to explain. There was no evidence that the men were alcoholics. The investigation confirms that patients with pernicious anemia have a special predisposition to cancer of the stomach. This is attributed not so much to the pernicious anemia in itself as to the fact that these patients have achylia.

Vinyl Ether Alone or in Combination with Ether Anesthesia in Adenotomy and Tonsillectomy. T. Strange.—p. 1012.
*Inoculation Hepatitis in Patients Treated with Dry Serum. G. Kjaergaard.—p. 1014.
Functional Training in Flat Foot. S. O. Brandt.—p. 1018.

Inoculation Hepatitis in Patients Treated with Dry Serum.—Kjaergaard says that follow-up of 542 patients treated with Danish pooled dry serum and observed for at least seven months revealed that in 23 (3.87 per cent) hepatitis occurred which might be attributable to inoculation with hepatitis virus during hospitalization. In a control group hepatitis occurred in 0.64 per cent. In the general population the incidence of hepatitis during the same period was between 0.3 and 0.4 per cent. The two groups of patients, however, are not directly comparable, and that the jaundice was caused by the serum infusions alone is regarded as doubtful. The frequency of hepatitis in the patients treated with dry serum corresponds closely to that reported by Marcussen in patients treated only with intravenous injections.

*Usefulness and Hazards of Treatment of Typhoid and Paratyphoid Fever with Chloramphenicol (Chloromycetin®). P. Mollaret.—p. 381.
Early Diagnosis and Estimation of Chances of Treatment of Cancer of the Stomach. R. Boller.—p. 384.
Endometriosis of Urinary Bladder and Estrus-Producing Compounds. H. Siegmund.—p. 387.
*Forty Cases of Progressive Peritonitis After Perforation of Appendix Without Fatality. J. Eberle.—p. 389.

Chloramphenicol in Typhoid and Paratyphoid Fever.—Mollaret treated 100 patients with typhoid and paratyphoid fever with chloramphenicol (chloromycetin®). Treatment was instituted with an initial dose of 2 or 3 Gm. Maintenance doses of 0.25 or 0.50 Gm. were administered in capsules every three hours. The temperature was lowered within one or two days, reaching 98.6 F. (37 C.) within about four days. Headache, listlessness and insomnia disappeared within 48 hours. Diminution in the size of the spleen was observed within four to five days. Digestive disturbances showed a somewhat slower response. Cultures of blood and of feces rapidly became negative. There were recurrences in 15 patients. Intestinal hemorrhages occurred in seven patients and intestinal perforation in one. Venous thrombosis developed in three patients in the course of the treatment. Encephalitis was observed in nine patients and jaundice in two. Death from circulatory collapse occurred in two patients. Necropsy revealed lesions similar to those which were observed in guinea pigs after the injection of typhoid endotoxin. The author believes that the drug exerts an indirect toxic effect by the massive liberation of endotoxin through the massive disintegration of the bacteria. Psychic disturbances, such as agitation, hallucinations and depression, were observed in all patients but subsided rapidly except in two patients who had to be transferred to the psychiatric ward for a prolonged period. Experience in the two fatal cases induced the author to desist from the initial dose and to use maintenance doses of 2 or 3 Gm. of the drug within 24 hours. Treatment should begin with smaller doses even in the patient in the advanced stage of the disease whose organism probably has been saturated with endotoxin. Treatment should be discontinued temporarily, for two or three days, in patients with subnormal blood pressure with a tendency to lowering of the differential pressure, acceleration of pulse and too rapid drop in temperature on the second or third day of the treatment.

Spreading Peritonitis After Perforation of Appendix.—Eberle reports 40 patients, 19 adults and 21 children, with spreading peritonitis due to perforation of the appendix. Operation was done with ether inhalation anesthesia in the majority of the cases. Exposure, isolation and removal of the appendix was carried out with as little trauma as possible, so that reparative walling off processes were not interfered with. Mopping and suctioning was done in the cecal area, but the abdominal cavity was not irrigated. A 5 mm. rubber drain was inserted in the wound, and peritoneum, muscles and fascia were closed tightly. One Gm. of streptomycin, 100,000 to 200,000 units of penicillin and 6 Gm. of sulfacetamide in 50 cc. of isotonic sodium chloride solution were injected through the drain, which was then removed. Continuous drip infusion was given for 48 hours, but as a rule sulfonamide compounds or antibiotics were not administered after the operation. However, two patients with perforation of a cecal abscess were given 0.25 Gm. of streptomycin every six hours and 40,000 then 20,000 units of penicillin by parenteral route every three hours for several days. Temperature was restored to normal within a few days; the boardlike hardness of the abdominal muscles subsided on the second or third day, and intestinal function was restored rapidly. There were no fatalities. Complete recovery occurred in 10 to 14 days. Douglas' abscess developed in two cases, requiring incision in one. No other complications were observed.

BOOK NOTICES

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Voluntary Prepayment Medical Care Plans. Revised 1950. Paper. Pp. 137. Council on Medical Service, American Medical Association, 535 N. Dearborn St., Chicago 10, 1950.

This is the most current revision of an annual publication inaugurated by the Council on Medical Service in 1946. It is designed primarily for those who are interested in a summary description of the organization, benefits and costs of the many voluntary health insurance programs in operation. The original edition listed 45 plans operating in 27 states and the Territory of Hawaii. That edition included only those plans sponsored by medical societies and/or coordinated with local hospitalization plans. Each succeeding revision has listed an increasing number of plans. The current revision lists 78 such plans operating in 45 states, the District of Columbia and Hawaii. In addition, this issue lists other types of plans domiciled and operating in the Dominion of Canada. A three page table of contents lists the plans by states and by sponsorship The introduction relates the early development of health insurance plans under medical sponsorship and also makes reference to early actions of the House of Delegates. Since voluntary health insurance is evolutionary, the introduction contains an explanation of some of the current experiments in this important field. Part 2 defines many of the terms used in explaining the various phases of these plans. Part 7 contains a summary depicting the growth in number of plans, growth in enrolment, a brief description of the various types of plans and the different methods of organization.

The Art of Real Happiness. By Norman Vincent Peale D.D., and Smiley Blanton, M.D. Cloth. $2.75 Pp 247. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1950

The authors, each well known in his field and author of previous successful books, have collaborated effectively in the production of this volume. They present a series of cases illustrating the commonest areas in which unhappiness occurs. The book opens with a discussion of new hope for a happier life, which the authors hold is possible for most persons of normal mentality. The love-hate duality is clearly defined and explained, together with the general principles underlying the attainment of peace of mind. Fundamental to the concept set forth in this book is the belief that there is a God from whom help can come if properly sought. From this premise, the authors have approached their cases in practice, and they so report them. The ability to relax after having done one's best, to stay healthy under pressure, to deal with depression (emotional) and anxiety, which are attributed mainly to guilt complexes, how to achieve a happy marriage (and to keep it that way), a solution for problem drinking, comfort in bereavement and the ability to grow older happily are all discussed optimistically yet realistically. The case report method and the solutions are clearly, interestingly and readably presented. The book can be recommended without reservation for lay readers whose problems fall within its scope.

Biological Actions of Sex Hormones. By Harold Burrows, C.B.E., Ph.D., F.R.C.S. Second edition. Cloth. $8.50. Pp. 615, with 8 illustrations, Cambridge University Press, Bentley House, 200 Euston Rd, London, N.W.1; American Branch, 51 Madison Ave., New York 10, 1949.

This is a coordinated summary consisting chiefly of laboratory studies on the biologic actions of the sex hormones in mammals. The treatise represents an exhaustive study thoroughly documented from the literature and from the author's experience of the effects of the gonadotropins, androgens and estrogens on living tissue and on the structure, function and behavior of the entire organism. As such, the book is chiefly of value to those conducting animal experimentation in this field or who require a source book.

Chirurgisch-gynakologische Grenzfragen: Physiologie und Pathologie der weiblichen Geschlechtsorgane in Beziehung zur Chirurgie. Von Prof. Dr. Herbert Uebermuth. Half-cloth. 9 marks. Pp. 168, with 16 illustrations. Georg Thieme, Thomaskirchhof 21, Leipzig C 1, 1950.

This book deals with borderline cases in gynecologic surgery. Many so-called borderline questions are propounded, and an attempt is made to answer these, the answers being based on both statistical data and the author's experiences. The book is divided into the following three parts: part 1, dealing with the female cycle and borderline surgical questions; Part A of this section, the influence of menstruation on operative procedures, and Part B, intraperitoneal bleeding (gynecologic) as an indication for surgical intervention; part 2, pregnancy and the surgical borderline questions, and part 3, gynecologic diseases and borderline cases. The pros and cons of surgical intervention during menses are discussed, and various authorities are quoted The author reports no complications in 126 major surgical procedures performed during menses. In 400 cases of intraperitoneal bleeding, only 55 were not caused by ectopic pregnancies; these 55 were of ovarian origin. In part 2 the author discusses hexobarbital sodium (evipan, evipal®) and ether anesthesia in cesarean section and states that the babies are born apneic when these are used.

The author stresses the point that infections, regardless of how slight, increase the possibility of abortion; therefore, abscesses and empyemas should be treated immediately. In cases of appendicitis associated with pregnancy, the author is opposed to conservative treatment even if an abscess has developed, and hence advocates early surgical intervention. He advises conservative treatment for six months after delivery in cases of "cholezystopathie." This term was confusing since it was not clarified. In gallbladder disease associated with pregnancy the author believes that surgery is indicated only if the patient's life is in danger, especially in those cases associated with common duct obstruction and empyema with impending peritonitis. Toxic diffuse goiter (Basedow's disease) is infrequent in pregnancy, and the author cites newer statistics showing an incidence of 0.2 per cent. Abortions, however, are frequent, occurring in 28.7 per cent of such cases. The book is well written and includes a few illustrative roentgenograms and microscopic sections. The subject of chemotherapy, however, should have been included The book can be recommended as a reference for those interested in surgery and gynecology.

The Causation and Treatment of Delayed Union in Fractures of the Long Bone. By Kenneth W. Starr, O.B.E., E.D., M.B., Surgeon, Sydney Hospital, New South Wales, Sydney. (This Jacksonian Prize Essay is Published with the Kind Permission of the Council of the Royal College of Surgeons of England). Cloth. $9. Pp. 215, with 109 illustrations. Butterworth & Co., Ltd., 4-6 Bell Yard, Temple Bar, London, W.C.2; The C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1947.

In this relatively small book there is an enormous amount of information on the physiology and pathology of bone. Part 1, The Morphogenesis of Bone, includes discussions of the structure and chemistry of bone, a short history of the research in reconstruction, deposition and resorption of bone and the relation between structure and function in bone morphology. In part 2, The Healing of Fractures, the author discusses the anatomic structures involved in repair as well as the process of repair following fractures. Part 3, on the etiology and treatment of delayed union, includes statistics, adjuvant therapeutic methods, the principles and management of difficult fractures, the treatment of closed and open fractures, septic fractures and the skin problem. The bibliography indicates the extent of investigation of literature. The title of the book might result in underestimation of its contents. Actually, healing of the long bone fractures is dealt with in detail and from every aspect, and often what appears to be merely academically important is developed so that its practical significance in the study of delayed union or nonunion is made evident. The style is pleasant, and the presentation is logical, so that the book is easy to read. The line of thought is clear throughout. Underlying the whole text is a vindication of the deductions of John Hunter, which seemingly have been obscured by clinical investigations of the past half century.

There appears to be little in the book which is original, but the author has succeeded in presenting some often forgotten observations in such a manner that the reader is made to realize the poverty of originality in research work done in the last few decades. The author has presented a challenge to modern orthopedists to add to the information which has been gathered about bone healing in recent centuries. It is an appeal for research of a more fundamental nature rather than complete dependence on clinical research, with its apparent limitations. The author is wont to blame the advent of radiography for this present day tendency.

The text is well illustrated, with numerous well chosen microphotographs and diagrams. The portion on treatment represents a report of a vast experience in dealing with all types of fractures. Some of the treatment is outdated. This is particularly true of the use of antibiotics, the knowledge of which has been increased so rapidly. The book is an excellent textbook for anyone interested in bone and joint surgery. It meets a long-felt need for a comprehensive treatment of the basic facts about growth and healing of bone.

Oxidation-Reduction Potentials in Bacteriology and Biochemistry. By L. F. Hewitt, Ph.D., B.Sc., F.R.I.C., Director, Serum Research Institute, Medical Research Council, Carshalton, Surrey. Sixth edition. Cloth. $4.50. Pp. 215, with 41 illustrations. The Williams and Wilkins Company, Mount Royal & Guilford Aves., Baltimore 2, 1950.

Formidable as the title appears, this volume contains, in addition to the technical procedures and definitions, much information which students of all the biologic sciences, including medicine, will find of practical value and interest.

Many biologic processes are either oxidation-reduction systems (i. e., involve exchanges of electric charges) or are affected by oxidation-reduction reactions. The chapter on Systems of Biological Interest includes discussions of sulfydryl systems, hemoglobin, several of the vitamins and hormones, as they are related to the subject. The chapter Bacteriological Applications covers many aspects of the electrode potentials developed and their effects on the metabolism of unicellular organisms. New chapters, not in the last edition, 1948, include applications of oxidation-reduction systems to p_H determinations, metabolic cycles of integrated enzyme systems and the mode of action of antibiotics and chemotherapeutic agents. The author presents the material in an interesting style seldom encountered in technical books, and the text is well annotated with extensive references.

Manual: Procedures and Layout for the Infant Formula Room. American Hospital Association M8-49. Paper. $1.50 to members; $2.25 to nonmembers. Pp. 52, with 3 illustrations. The Association, 18 E. Division St., Chicago 10, 1949.

This manual is designed to guide hospital executives in planning, installing, equipping and administering a formula room. It was prepared under the guidance and with the assistance of members of a committee appointed by the Council on Professional Practice of the American Hospital Association. The important hospital problem having to do with the prevention and control of diarrheal disorders requires, for its solution, the proper organization and operation of the formula room. Sufficiently detailed information is reported to make this a practical and useful guide. In the preparation of this manual the committee has made an important and useful contribution.

The Salt-Free Diet Cook Book. By Emil G. Conason, M.D., and Ella Metz. Cloth. $3. Pp. 137. Lear Publishers, 105 E. 15th St., New York 3; Distributed by Crown Publishers, 419 Fourth Ave., New York 16, 1949.

This book consists chiefly of a group of menus with estimates of sodium content. Usefulness of this book is limited basically by the fact that more information is needed for the development of truly representative figures for the sodium content of individual foods.

The Future in Medicine: The March of Medicine, 1949. Number XIV of the New York Academy of Medicine Lectures to the Laity. Cloth. $2.50. Pp. 160. Columbia University Press, 2960 Broadway, New York 27, 1950.

The five articles that make up this volume cover phases of medicine that embrace law, sociology, physics, criminology, hematology, immunology, anthropology and psychiatry, so that the general public and members of the medical profession may review important recent developments which unquestionably will influence the future in medicine. These essays have been prepared by renowned authorities in their field. Their contributions are provocative and worthy of reading by all who have an interest in medical affairs. The volume well deserves a place with the others that make up this series and should be handy in libraries or on the night table.

Rose's Laboratory Handbook for Dietetics. Revised and Rewritten by Clara Mae Taylor, Ph.D., Professor of Nutrition, Teachers College, Columbia University, New York, and Grace MacLeod, Ph.D. Fifth edition. Cloth. $5. Pp. 358. The Macmillan Company, 60 5th Ave., New York 11, 1949.

This useful book has been expanded to include the more recent quantitative data on food composition. It is intended for use by teachers, community and public health nutritionists, the hospital dietician, the advanced student of nutrition, doctors interested in nutrition and any other persons who may be interested in the quantitative aspects of the national food supply and its nutritive value.

Part 1 includes a brief discussion of functions of food and food requirements for different age groups during various activities. Part 2 consists of common problems in dietary calculations. Reference tables make up part 3. These tables include such useful data as equivalents for weights and measures, vitamin equivalents, weight-height age tables for various age groups and conversion tables for common measures. Part 4 includes many tables of food composition. These tables give protein, fat, carbohydrate and caloric values for many common foods, along with such values as essential amino acids, minerals, oxalic acid, vitamin D, niacin, biotin, choline, pantothenic acid, paraaminobenzoic acid and pyridoxine. There is also in this section a useful table of approximate vitamin losses in cooking foods. For the most part this book is composed of tables and charts, which, although there is some repetition of data, appear entirely adequate. It also contains the necessary material to give the reader a basic understanding of the text.

Speech Problems of Children: A Guide to Care and Correction. Edited by Wendell Johnson, Ph.D. Prepared for the National Society for Crippled Children and Adults, by the American Speech and Hearing Association. Cloth. $3.75. Pp. 265, with 4 illustrations. Grune & Stratton, Inc., 381 4th Ave., New York 16, 1950.

Prepared according to a carefully developed plan to insure an authoritative approach, this book is the product of 11 authors under the editor. Included in the routine was a survey of each chapter by two professional consultants. As a result, the reader is assured of receiving information that can be considered accurate and generally acceptable, although, as is acknowledged, not all schools of thought regarding some aspects are necessarily represented.

The general problem of speech difficulties is broken down into its most important components. Included are chapters on functional disorders of articulation, speech retardation, cleft lip and cleft palate, cerebral palsy, hesitant speech, children of foreign tongues and children with impaired hearing. The general problem is clarified in the opening chapter, a survey by Frank P. Bakes, Ph.D., and there are general chapters on speech as it is acquired in the average home and in school surroundings. After each of the chapters dealing with specific subjects there is an adequate list of references. Interesting features are inclusion in the introductory section of a special message to parents and "A Word to All Concerned," in which general orientation is provided. Although directed perhaps primarily to parents, the volume contains material of equally great interest to social workers, nurses, teachers and physicians. The National Society for Crippled Children and Adults and the American Speech and Hearing Association are to be congratulated on having made an important contribution to better and more general understanding of speech problems and their solution.

Psychology and Mental Health: A Contribution to Developmental Psychology. By J. A. Hadfield, M.A., M.B., Ch.B. Cloth. $2.75. Pp. 444. The Macmillan Company, 60 5th Ave., New York 11; George Allen & Unwin, Ltd., Ruskin House, 40 Museum St., London, W.C.1, 1950.

This book reflects the concepts and practice of an experienced worker in the field of medical psychology, as well as the sub*stance of certain lectures given by him in the course of 20 years* at the University of London. The author deals primarily with psychopathology and the causes of mental disorder, as they relate to mental health. He confines himself to that segment of psychiatric inquiry pertaining to the psychoneuroses and behavior disorders, since in his judgment these are derived for the most part from environmental conditions and are therefore more accessible to prevention and cure than the more constitutionally determined psychoses. He lays special emphasis on predisposing causes in early childhood and on the psychology of the individual. He believes that by working out in the individual the causes of disorder and breakdown, clues may be found to causes of neurosis and unrest in the community.

The author's approach is dynamic, influenced by the teachings of Freud, Jung and Adler, but considerably modified by convictions based on his clinical practice. It is his thesis that the basic cause of the psychoneuroses is the feeling of deprivation of love, the need for protective love and security being in fact of far greater importance than repressed sexuality. This feeling of deprivation gives rise to morbid reactions—anger, self pity, hate, power fantasy, depression and pride—which are then repressed in favor of a moral superego, with resulting dissociation of personality and the emergence of psychoneurotic symptoms. The author attempts to show how this mechanism operates in the major clinical pictures—psychosomatic disorders, traumatic neuroses, hysteria, anxiety states, anxiety hysteria, obsessional neuroses, personality disorders and sex perversions and aberrations. In the process of treatment, he accepts in the main Freud's concepts of conflict, repression and projection and the use of free association. Free association, rather than dreams, is the gateway to the forgotten past. He avoids the process of transference as being neither necessary nor desirable and concentrates on direct, reductive analysis. This consists of going back to the original experience which gave rise to the repressed emotions, releasing the latter toward the person or experiences to whom or to which they properly belong, with subsequent redirection to useful ends. This is a provocative and rewarding book, effectively organized and presented, which contributes much to the cause of a more practical, middle-of-the-road, analytic psychiatry.

Sexual Fear. By Edwin W. Hirsch, B.S., M.D., Attending Urologist, Englewood Hospital, Chicago. Cloth. $3. Pp. 307. Garden City Publishing Co., Inc., Garden City, New York; 14 W. 49th St., New York 20, 1950.

Because the author uses a hopeful, encouraging approach in the chapters dealing with specific sex-linked fears, this book is well suited for the average lay reader. In the first six chapters, sex life and the development of sexual fears are traced historically from Babylonian days down through the Middle Ages to provide a background of understanding in relation to modern attitudes on sex. The first widespread recognition of syphilis with the siege of Naples in 1494 is described in an interesting discussion that includes other theories regarding the actual origin of this venereal disease.

Considered in the next six chapters are subjects of common discussion and all too frequent misunderstanding, including frigidity, the male change of life and impotence, this last chapter being enlivened with numerous specific case reports presented in nontechnical terms. This method is employed to some extent also in the final chapter, treatment of sexual fear by psychomatics, a term coined by the author to designate his system of investigating and correcting disordered sexual function due primarily to sexual fear. Psychomatic refers, Hirsch explains, not only to the mind, body and environment but also to "influences" outside and within the self. An extensive bibliography is provided for the reader interested in source material. Physicians should find this volume satisfactory for recommendation to patients with sexual maladjustments. It does an effective job of correcting the many ignorant conceptions concerning sexual function.

Genito-Urinary Surgery. By Sir John Thomson-Walker, D.L., M.B., C.M.Ed., Consulting Urologist, King's College Hospital, London. Third edition edited by Kenneth Walker, M.A., M.B., B.C., Urologist, Hornsey Central and Dartford County Hospitals, London. Cloth. $15. Pp. 956, with 340 illustrations. Paul B. Hoeber, Inc., Medical Book Department of Harper & Brothers, 49 E. 33rd St., New York 16, 1950.

This has been regarded as an outstanding textbook in urology since it was first published in 1914. The author was one of the most competent urologists of his time, and his thorough knowledge and wide experience are well reflected in the pages of this book. The present edition maintains the general excellence of the original volumes. Although the editor has attempted to bring the material up to date, it is evident that many of the recent developments in urology have not been included. It will be noted that but few of the references given at the end of the chapters were dated after 1935. This deficiency is apparent in the chapter on genitourinary infection and its treatment. There should be a more extensive discussion on the use of sulfonamides and the antibiotic preparations now in common usage. The chapter on the various methods of prostatectomy is inadequate. A more complete consideration of recent developments in this field, including transurethral prostatic resection, would be desirable. Errors may be noted in the discussion of the historical development of several urologic procedures, as, for example, in the origin of excretory urography. The book remains as one of the standard textbooks in urology and deserves a place in a representative medical library.

Die Leptospirose: Eine kurze Darstellung für Arzte, Tierärzte und Gesundheitsbehörden. Von Prof. Dr. med. W. Rimpau. Monographien der "Medizinischen Klinik," Heft 8. Paper. 10 marks. Pp. 157, with 15 illustrations. Urban & Schwarzenberg, Thierschstrasse 11, Munich 22; Meinckestr. 13, Berlin W. 15, 1950.

This monograph contains an introduction and chapters on the morphology and biology of the Leptospiras; immunology, distribution, clinical aspects, pathology, epidemiology, and prevention and treatment of leptospirosis. The first part of the book, which is devoted to the causative organisms, contains much valuable information on observations made in central Europe and, before the war, in the Far East, while North American, Spanish, Latin-American and postwar Dutch publications are either disregarded totally or utilized only to a small extent. The clinical picture of leptospirosis is classified as leptospiral fever, renal form, hepatic form, meningitis, hepatorenal syndrome, bronchopneumonic form and the questionable chronic form. Fifteen fever curves illustrate the course of the disease. The symptomatology and pathology of the disease are discussed *to some length without any reference to information avail*able in standard American texts. The chapter on epidemiology contains a number of interesting observations made in Germany and Switzerland, especially on the relation of soil, temperature, moisture and leptospirosis in animals. The therapeutic recommendations are up to date, although one could add much to the description of prophylactic measures. The book was carefully printed on good paper.

Researches on the Radiotherapy of Oral Cancer. By Constance A. P. Wood and J. W. Boag. Medical Research Council, Special Report Series No. 267. Paper. 12s.6d. Pp. 148, with 77 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W.C.2, 1950.

This is a special report of a study of the Radio-therapeutic Research Unit. The purpose of the study was to compare the effectiveness of a radium beam unit with roentgen therapy at 185 to 200 KV in causing tumor regression. The report is in three sections. The first section compares the results of treatment with the beam unit and roentgen therapy of cancers of the mouth and throat. A number of patients were treated on one side with the beam unit and on the other with the roentgen therapy unit, for comparison of the skin reaction in the same patient. The second section deals with serial biopsies of oral carcinoma as an aid in obtaining prognosis and response to radiotherapy. The third section presents a statistical analysis of the response to treatment of 641 patients treated in the unit who were suffering from cancer of the mouth and throat. A statistical method of estimating the final results of a clinical experiment before long term survival figures become available is also described. The report is well written. Detailed data are given on the content of the studies. It should serve as an excellent reference. Numerous figures and tables are included. Of the 30 plates, four are in color. One of the author's conclusions is that, if the glandular region were to receive a dose of the same order as the primary lesion, the glands would offer no greater resistance to irradiation than the primary lesion.

Administration of Schools of Nursing. By Dorothy Rogers Williams, M.A., R.N., Lecturer, Administrator of Schools of Nursing and Nursing Services, Frances Payne Bolton School of Nursing, Western Reserve University, Cleveland. Edited by Isabel M. Stewart, M.A., R.N. Cloth. $4. Pp. 288. The MacMillan Company, 60 Fifth Ave., New York 11, 1950.

This book, devoted to the administration of schools of nursing, does not attempt to include the administrative functions of the related field of hospital nursing service. It is purposely restricted to educational activities and to the changing pattern of nursing education, which today requires more and more the full attention of those who direct the training of the professional nurse. Beginning with the basic concepts of organization, the author describes in clear and logical manner the present trends in the organization of collegiate and hospital schools of nursing, the relation of the controlling groups, the selection and administration of the faculty, administrative planning for the recruitment and guidance of student personnel, student health, organization of the curriculum, teaching methods, costs and sources of income, school publicity, professional and legislative relations, accreditation of training programs and the qualifications and preparation necessary for the nursing school administrator.

The purpose of the many details of organization and administration described in this book is to aid the directors of individual schools to develop and maintain sound educational programs in keeping with the changing pattern of professional nursing standards. To this end the book will be of valuable assistance to nurses already directing schools and to those who are preparing themselves for administrative duties. It will also be welcomed by hospital directors, physicians and others who may be closely associated with nursing schools in an administrative or advisory capacity. The reader will find a helpful summary at the end of each chapter as well as an extended list of publications for further reference.

Woman's Surgeon: The Life Story of J. Marion Sims. By Seale Harris, M.D. With the Collaboration of Frances Williams Browin. Cloth. $5. Pp. 432, with illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1950.

This biography of Marion Sims, the father of modern gynecology, is a fascinating story of a great man written by one of his admirers. The author is a distinguished physician, teacher and investigator as well as a fellow Southerner, who first became interested in Sims when he was only 15 years old. He drove his father, who was a physician, on his daily rounds and listened to the biography of Sims. Dr. Harris' interest in the "woman's surgeon" continued over the years, and this biography is the result of much study and investigation.

Marion Sims was a frail youth born in a well-to-do family. He had no particular interests. His father urged him to study law, and his mother was anxious that the sensitive youth should become a preacher. However, neither of these professions intrigued him, and he studied medicine reluctantly and with little enthusiasm. The first years after graduation were uninteresting and unrewarding. The highlight of this period was his marriage to his childhood sweetheart, who gave him much encouragement in his life's work and remained his faithful partner and helpmate all his life. He finally settled in Montgomery, Ala., where he soon developed an interest in surgery, for which he had much innate ability. His interest was aroused in the wretched complication of vesicovaginal fistula, a common occurrence because of the poor obstetric care. He found this condition in three of his slaves, and these unfortunate women were the willing and trusting victims for 30 attempts at the repair of their fistulas. His persistence, hard work and the use of silver wire for suture effected a cure in one of his patients after 29 failures. Knowledge of his surgical prowess soon spread throughout the South, and he developed a large practice. However, the weather and the recurrence of a chronic ailment for which he had to spend long periods in bed finally decided him to liquidate his interests in Montgomery and move to New York.

The weather and the professional environment worked wonders for Marion Sims. He soon acquired a large practice, because his reputation had preceded him. There were many women, rich and poor, who had sustained childbirth damage or who had other pelvic complications which he could cure. He was a brilliant surgeon and had a special talent for developing new instruments and technics to make his surgery more spectacular. He succeeded in recruiting some of his wealthy patients to help him build a hospital for women's diseases. The Woman's Hospital soon became a mecca for visiting doctors from everywhere. Much of the early history of gynecology was written here by Sims and his early disciples, Emmett, Thomas and Peaslee. He considered the institution his own creation and his home. He soon began the practice of spending longer and longer periods in Europe, and he gained loyal followings in Paris and London. His consulting rooms were filled with international celebrities, including many women from the royal families of Europe. Because of constant arguments with his colleagues and the board of governors of the hospital, his late years were unhappy. In a fit of temper he resigned from the hospital staff, a decision he regretted promptly, but his resignation was accepted. This was a blow from which he never recovered. The author has done a magnificent job in picturing the "woman's surgeon" as a genius in American medicine and yet a human with many human failings. He was selfish; he loved fame and power, and yet he was a kindly man ready to do everything possible for the less privileged. Every physician will enjoy this biography for leisure reading.

Die Wirkungseinheit des Lebens: Eine Einheits-, Spezial- und Ganzheitsbetrachtung der Lebensvorgänge unter normalen und krankhaften Bedingungen. Von Dr. med. Ludwig Seitz. Cloth. 33 marks. Pp. 500, with 54 illustrations. Urban & Schwarzenberg, Thierschstrasse 11, München 22; Meinekestr. 13, Berlin W. 15, 1950.

As indicated in the title, the author has attempted to define the common denominator of all living processes under normal and pathological conditions. He attempts to do for biology what Einstein with his theory of relativity did for physics. That he has not succeeded in reaching this goal is not surprising when one considers how remote from mathematical expression most biologic phenomena are. The author examines, albeit superficially, a wide domain of biologic knowledge, including topics such as the unicellular organism, cosmic and biologic rhythms, the cell as a chemical laboratory, chemical and biomorphological structures, genetics, the gonads, chemohormonal factors in pregnancy, the reflexes, Cushing's disease, the role of the vegetative nervous system in somatic disease, the psyche and a comparison of the modern state and cellular organism. To one philosophically inclined, this range of subject matter will present many points of interest. However, despite the author's constant repetition that all living processes have a common basis, the reader is left with the tantalizing thought that the essence of life cannot be expressed by any simple formula, as promised by the author in his preface. References to the literature are sparse and not critical; the illustrations are schematic drawings which oversimplify and mechanize the physiological principles which they illustrate.

Chemotherapie der Tuberkulose mit den Thiosemikarbazonen. Von Gerhard Domagk. Unter Mitarbeit von C. Arold, et al. Cloth. 60 marks; $14.30. Pp. 405, with 257 illustrations. Georg Thieme Verlag, Diemershaldenstrasse 47, (14a) Stuttgart-O; Agents for U. S. A.: Grune & Stratton, Inc., 381 4th Ave.; New York 16, 1950.

This German volume is the result of studies initiated in the hope of establishing a chemotherapy for tuberculosis. Experimental tests were performed exactly and were intended to build a causal therapy for tuberculosis similar to those for other bacterial infections. With the basic acknowledgment of differences between animal experiments and the treatment of tuberculous man, it was recognized that if the semicarbazones, whose specific action was demonstrated in 1946, could affect a human type of tuberculous infection in the highly susceptible guinea pig, such materials in harmless doses might prove useful in the various forms of tuberculosis in man. While the action of streptomycin is conspicuous in guinea pig tuberculosis, paraaminosalicylic acid (PAS) is poorly tolerated by these animals and is not as acceptable as the semicarbazones, even though it is tolerated better in less susceptible species. Thus the possibility of a causal therapy of tuberculosis exists.

This volume consists of a series of 14 monographs by various authors which to a great extent originally appeared in German periodicals. It is concerned primarily with the results obtained with amithiozone (Tb. 1-698). The initial chapters occupy 141 pages and were written by Domagk, who introduced amithiozone. They include monographs on the bacteriology of the tubercle bacillus, especially its culture and determination, followed by the pathology of tuberculosis in man and, finally, the chemotherapy of tuberculosis, particularly the new semicarbazones. Consideration is given to streptomycin, paraaminosalicylic acid and amithiozone, with the conclusion that amithiozone is second to streptomycin in value and possesses certain advantages, such as length of use and the nondevelopment of resistance by the bacilli. Favorable results from the use of amithiozone are recorded in lupus by Kalkoff, in mucous membrane (upper respiratory tract) tuberculosis by Arold, in lymph gland disease *and intestinal tuberculosis by Kuhlmann and Knorr, in urogenital* tuberculosis by Boshamer, in bone and joint tuberculosis by Ullmann, in pulmonary tuberculosis by Klee, Melzer, Rühs, Köthe and Jahnke, and Kuhlmann and Lemberger, and in cavernous tuberculosis (local application) by Malluche. In the final monograph, Heilmeyer cites beneficial results from the use of amithiozone in nontuberculous cases, especially chronic rheumatoid arthritis, and records a study of the plasma colloids with this treatment. Though the results cannot be judged to be anything more than beneficial, the monographs disclose an exhaustive study of a new chemotherapeutic compound applied both experimentally in animals and for treatment in man. Although one may not agree entirely with some of the conclusions, the monographs present sufficiently detailed records for the reader to be able to make his own conclusions.

That such a study should emanate from a country decimated so recently by war is astonishing, and yet this volume is doubly interesting in that professional and scientific persons could not be stifled completely, regardless of the political situation. In view of the excellence of the presentation of these monographs and the high quality and durability of materials, even a critical reviewer must conclude that they contain much to stimulate study and to guide future chemotherapeutic possibilities in tuberculosis. The volume presents scientific information and, as such, merits particular consideration for possible corroborative evaluation and productive elaboration.

The Respiratory Function in Laryngectomized Patients. By Rutger Heyden. Acta otolaryngologica, Supplementum LXXXV. Paper. Pp. 76, with 35 illustrations. Lund, 1950.

This magazine supplement, dealing with respiratory function in patients subjected to laryngectomy, is based on an investigation of 44 patients treated for cancer of the larynx during the period 1940-1949 at the Karolinska Sjukhuset in Stockholm, Sweden. The author made spirometric determinations of lung volume and studied respiration with work tests on a bicycle ergometer. Two thirds of the patients examined were able to perform physical work; 58 per cent of them rarely had respiratory infections. The subjects who had undergone laryngectomy appeared to have a somewhat low pulmonary vital capacity.

Biochemical Aspects of Genetics: A Symposium Held at the Westminster Hospital Medical School, London, on 12 February 1949. Organized and edited by R. T. Williams. Biochemical Society Symposia No. 4. Paper 6s; $1.50. Pp. 60, with illustrations. Cambridge University Press, Bentley House, 200 Euston Rd., London, N.W.1; American Branch: 51 Madison Ave., New York 10, 1950.

The symposium, according to one of the speakers, gave a clear demonstration of the connection between genetics and biochemistry in the interpretation of biochemical mutations. The basic concept of the current hypothesis for such mutations is recognition that the genetic abnormality consists of a blocking of a normal metabolic pathway owing to the absence or decrease in concentration of a specific enzyme. Garrod, early in this century, pioneered the work in this field in his study of ochronosis and other inborn metabolic disorders. Discussions on genetic control of biochemical synthesis, chemically induced mutations, gene action and mutation, biochemical genetics of micro-organisms and adaptation, mutation and segregation in the formation of bacterial enzymes are included among the various aspects of the subject.

Le Cancer du corps utérin. Publié sous la direction de P. Chalnot. Avec la collaboration de M. Beau, et al. Questions gynécologiques d'actualité. Pp. 247, with illustrations. L'Expansion scientifique française, 23, Rue du Cherche-Midi, Paris 6e [n.d.].

This is a remarkably complete discussion of all phases of endometrial cancer, with emphasis on newer methods of treatment, by 16 French physicians. The book proceeds logically from an anatomic consideration of the uterus, with emphasis on the lymphatic system, through pathology, possible etiological factors in endometrial cancer, methods of diagnosis, including newer methods of hysterosalpingography (a debatable procedure, but apparently useful in the hands of experts), to treatment.

Emphasis in treatment in the past has been on adequate irradiation, particularly with radium. This is well covered in *the present volume. Considerable emphasis is also laid on surgi*cal therapy and on combined irradiation and hysterectomy. The advantages and disadvantages of all procedures are discussed, and statistics drawn from studies made all over the world are presented to show that, in the hands of the authors, combined surgical-irradiation therapy offers the best results. The data on which this conclusion is based must be scrutinized with some care. Whether any series of cases is comparable to any other series of cases is difficult, at best, to determine; and when many of these series are obtained from the literature, it becomes almost impossible to judge their comparability. Despite these statistical drawbacks, it does appear that the French have had good success with a combination of irradiation and hysterectomy in treating endometrial cancer. The data are well presented, and considerable detail regarding procedure is given. Anyone interested in gynecologic surgery or in tumors will find this volume of interest.

Clinical Pathology: Application and Interpretation. By Benjamin B. Wells, M.D., Ph.D., Professor of Medicine, University of Arkansas School of Medicine, Little Rock, Arkansas. Cloth. $6. Pp. 397, with 32 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1950.

This book is written by a well qualified internist for clinicians, pathologists and medical students. It does not present discussions on technics but offers information on the use and evaluation of laboratory procedures in relation to clinical medicine. Included are chapters on laboratory studies in the surgical and obstetrical fields. Dr. Wells writes, "The practitioner must know at least three things about every laboratory procedure he expects to use: (1) when to use it, (2) how to interpret the results and (3) what technical or physiologic limitations must be taken into account in the interpretation." The procedures covered in the book are available to most physicians. The volume is handy in size and well printed. The views expressed by Dr. Wells are in agreement with those generally held. The book is well written.

The Microscopic Diagnosis of Human Malaria. Part I: A Short Descriptive Atlas of Thick-Film Diagnosis. By John W. Field. Studies from the Institute for Medical Research, Federation of Malaya, No. 23. Paper. $5. Pp. 117, with 81 illustrations by Yap Loy Fong. H. T. Ross, Government Printer, Kuala Lumpur, 1948-1949.

This atlas is for the diagnosis of those types of human malaria encountered in Malaya, including Protozoa falciparum, P. vivax and P. malariae. It includes short accounts of the life histories of the malaria parasites, detailed systematic descriptions of each parasite in lysed, Romanowsky-stained thick films and technical procedures for preparation, staining and examination of the material. It is well illustrated with composite original drawings made with the aid of the microscope and the camera lucida from films stained by Giemsa's or Romanowsky's method. Unfortunately, costs and technical difficulties in Malaya prevented the use of color.

QUERIES AND MINOR NOTES

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

BLOOD PRESSURE OF MORE THAN 300

To the Editor:—An 89 year old white man with arteriosclerosis was seen in 1939 with what was thought to be coronary occlusion, from which he made an uneventful recovery. In April 1950 cardiac decompensation was noted, with a rapid regular rate, edema of the legs, enlarged heart and no murmurs. I could not determine the blood pressure in either arm, nor could I obliterate the radial pulse with a mercury manometer raised to 300 mm. Blood pressure in the legs was not obtainable because of edema; there was no pulsation in the dorsalis pedis artery. Roentgenograms of both arms showed considerable calcification in both brachial arteries. My theory is that these arteries are so calcified that it is impossible to compress them with the blood pressure cuff. Two older internists of wide experience have not encountered this condition, and I am unable to find in the literature anything relative to such a condition. How is blood pressure in the leg properly determined, and what are considered normal values?

M.D., Minnesota.

ANSWER.—It is doubtful whether the failure to obliterate the pulse with a cuff pressure of 300 mm. of mercury is due to the rigidity and incompressibility of sclerotic arteries. One may be almost certain that the systolic tension is actually over 300 mm. of mercury. Levels as high as this, though unusual, are not exceptionally rare. There should be no significant risk in applying greater pressure with a special manometer. Such excessively high levels are not incompatible with the advanced age of the patient.

No mention is made in the query as to any change in note (phase 4) or disappearance of sound (phase 5) as the tension in the cuff is reduced. If one assumes this patient's systolic tension to be somewhere between 300 and 400 mm. of mercury, a diastolic pressure of 150 to 200 should be expected. Anything lower would suggest aortic valve incompetence and regurgitation. The diastolic tension cannot be determined by palpation.

The arterial tension in the legs may be difficult to measure. A wider cuff is needed around the thigh. Sounds in the popliteal space are often very faint, especially when obesity or edema occurs. However, except in cases of coarctation of the aorta, the tension in the legs is 20 to 50 mm. higher than in the arms, when measured with the patient in the recumbent position. If tension is determined with the patient standing erect, the difference is even greater, because of the increased hydrostatic pressure. Readings of tension which are lower in the legs than in the arms are pathognomonic of coarctation of the aorta.

PREOPERATIVE TREATMENT FOR CESAREAN SECTION

To the Editor:—I would like the opinion of (1) anesthesiologists and (2) obstetricians with regard to preoperative medication for cesarean section and especially concerning its use with spinal anesthesia. Is 1/6 grain (0.01 Gm.) morphine sulfate and 1/150 grain (0.44 mg.) scopolamine hydrobromide excessive as preoperative medication if given one hour preoperatively to a 125-130 pound (57-59 Kg.) pregnant woman who has a cephalopelvic disproportion? What are the effects on the infant of these drugs as given preoperatively? Should barbiturates be used?

M.D., New Jersey.

ANSWER.—The anesthesiologist does not feel the need for the preoperative use of morphine and scopolamine when spinal anesthesia is to be used, if the anesthesia is adequate by itself for the obstetric patient in labor. Use of these agents, moreover, is undesirable from the point of view of interference with spontaneous respirations in the newborn. The more cephalopelvic disproportion the patient may have—or in other words, the more prolonged the delivery—the less desirable it is for the infant to be subjected to the effect of morphine and scopolamine hydrobromide. It is true that a barbiturate, used in a small dose, is less undesirable than morphine and scopolamine hydrobromide, yet it is undesirable to have a noticeable barbiturate effect produced in the mother, because the newborn will not breathe as spontaneously as he or she would have done without medication. For elective cesarean section, 50 or 100 mg. of meperidine (demerol®) hydrochloride has proved satisfactory and less depressive for the infant than morphine or barbiturates would be. If a barbiturate is used peroperatively in cesarean section, it is preferable to keep the dose to 1½ grains (90 mg.) of pentobarbital sodium (nembutal®).

CLOTTING TESTS BEFORE TONSILLECTOMY

To the Editor:—Is there any reason to continue the performance as a routine procedure of the clotting and bleeding time tests for tonsillectomy in children?

Lazaro Benavides, M.D., Mexico, D. F.

ANSWER.—Routine evaluation of the clotting and bleeding time prior to tonsillectomy in children may reveal an unsuspected hemorrhagic disease. In hemophilia the coagulation or clotting time is usually prolonged; in the various types of purpura the result of this test is usually normal. In thrombocytopenic purpura the bleeding time is usually prolonged, while in hemophilia it is normal. Probably there are children with a bleeding tendency who do not fall into these categories whom it might be well to detect before operation. Determination of the clotting and bleeding time is the only way in which such tendencies might be discovered before operation.

In most of the leading children's hospitals, the temperature, pulse and respiration rates are noted and a urine specimen is examined prior to operation. Formerly it was also common for specialists to obtain roentgenograms of the chests of the children prior to tonsillectomy in an attempt to ascertain whether an enlarged thymus gland was present, which might result in a fatality from an anesthetic or the operation. This examination has been largely discontinued.

GENERALIZED CONVULSIONS

To the Editor:—On an airplane trip home from my fifteenth college reunion a week ago I felt sleepy as we started to land at Dayton. I woke up to learn from the hostess that I had had "a generalized convulsion which lasted about three minutes, during which "your pulse rate was about 120." A physician boarded the plane, took my blood pressure, listened to my heart, then asked that I be given a dimenhydrinate (dramamine) tablet and ¼ grain (15 mg.) of phenobarbital. He stated that he found nothing abnormal. I felt fine save for the fatigue which one expects after such vigorous conviviality with school mates. I awoke in my own bed about 15 hours after this experience to find my wife in hysterics and a physician neighbor drawing blood from my vein. I felt rested, but was told that I had again had a convulsion. Two neurologists found no evidence of disease. An electrocardiogram showed a 7 second rhythm; I had taken three pentobarbital capsules (0.28 Gm. total) at bedtime, seven hours before the electrocardiogram was taken, and also before the convulsions. I am 37. The only thing in my history worthy of note is that I have a large cranium and I like soft drinks. Laboratory studies show nonprotein nitrogen 34 mg., blood sugar 108 (as the attack subsided) and eosinophils 8 per cent.

M.D., Pittsburgh.

This inquiry was referred to two authorities, whose respective replies follow.—ED.

ANSWER.—It would be a serious mistake to pass off these two generalized convulsions lightly or to attribute them to some relatively innocuous agent such as pentobarbital. Pentobarbital, even in fairly large doses, does not give rise to convulsions. The situation demands thorough investigation from a neurological and neurosurgical standpoint. The inquirer should place himself under the care of some neurologist or neurosurgeon and follow his recommendations.

ANSWER.—Although the 8 per cent eosinophil count is somewhat suggestive of the presence of allergy and the episodes presented have been on rare occasions claimed to be due to allergic causes, it would be presumptuous and hazardous to consider allergy the most important cause. It is decidedly more important that this condition be investigated from the neurologic, psychogenic, vascular or other medical approach.

ELECTROSHOCK TREATMENTS

To the Editor:—A patient had a series of electroshock treatments concurrently with subshock doses of insulin. She has heard that this form of treatment shortens a person's life and causes permanent physical damage. Is there any evidence to disprove this belief?

M.D., Arizona.

ANSWER.—Numerous brains of both man and animal have been examined after electroshock treatments, and there has been no significant change found in the architecture. The same is essentially true with insulin shock, particularly the subshock variety. Occasionally in either, oftener with insulin, there are a few changes in and about the blood vessels, some glial changes, but no significant permanent damage.

Fractures of bones, essentially mild compressions of the vertebrae and rupture of muscles do occur, but they, too, are inconsequential. When the bones are osteoporotic the vertebral column should always be examined roentgenographically before treatment. Treatment may be pursued with the use of curare or curare-like substances to avoid the violent convulsion.

The electroshock treatment appears to have no effect on a normal heart. Patients with severe myocardial damage have been treated successfully without any untoward effect on the heart. Here the decision depends on the circumstances. When the patient is literally thrashing himself to death, it becomes a life-saving, hence justifiable, risk. When a patient known to have cardiac damage develops a psychosis which is resistant to all conservative therapy and shock treatment is necessary, treatment may go on, with curare used as mentioned above or a sedative like a barbiturate given intravenously. This moderates the convulsion. Curare supervised by a competent anesthetist is preferred. This, of course, means having available a mechanical respirator, and, if necessary, neostigmine. Occasionally death occurs from myocardial infarction.

After intensive electroshock treatment the patient has a sense of memory loss. The actual period of treatment frequently is an island of blankness. Spontaneous memory seems to be more affected than that of learned didactic material; yet after a few months the patient seems to recapture everything but the period of treatment. All except those who had previous organic brain damage are able to return to their pre-illness status, or occupation, if the electroshock was effective. Subshock with insulin combined with electroshock adds no further changes except that the deep confusion often associated with intensive electroshock treatment comes on more slowly and clears more rapidly.

EPILEPSY AND OSTEOGENESIS IMPERFECTA

To the Editor:—A 9 year old boy has had osteogenesis imperfecta of the congenital type. He sustained his first spontaneous fracture at the age of 9 months and since then has had eight more fractures. The last of these, a year and a half ago, followed sufficient trauma to cause the fracture of a normal bone. We believe that this condition is now in remission. In addition, from 1944 to 1947 the child had 17 grand mal type convulsions, some following febrile illnesses. He has been studied at a reputable clinic, and it was considered that he suffered from idiopathic epilepsy. Electroencephalograms of the father showed an epileptic pattern, though he has never had frank convulsions. The paternal grandfather suffered from some type of convulsive disorder. There is no other history of spontaneous fractures among either parents or grandparents, nor have I seen any other family members who had blue scleras. The parents of this boy want another child. They have received conflicting advice from several sources. What is your recommendation?

M.D., South Carolina.

Answer.—Many pedigrees are on record showing a high incidence of osteogenesis imperfecta among both close and distant relatives; in some families it has appeared in as many as five generations. Epilepsy is not always inherited. In the case just cited, however, it would appear to be familial in origin. Again, as in the case of osteogenesis imperfecta, there are many family trees on record which reveal numerous cases of epilepsy among blood relatives. The existence of either of these diseases alone should be a sufficient contraindication to future childbearing.

HIRSUTISM

To the Editor:—A woman aged 35 complains of having to shave twice daily because of a beard of coarse hairs, increasing since onset six years ago. There are no other masculinizing signs, such as change of voice, temperament, enlargement of the clitoris or male distribution of pubic hair and no menstrual changes. The patient blames her hirsutism on progesterone, of which she received a total of three injections of 10 mg. each at monthly intervals prior to the appearance of the hair. Can you refer me to scientific studies which confirm or disprove this contention?

M.D., California.

Answer.—There are no data in the literature which suggest that the administration of progesterone causes hirsutism. The patient should be carefully studied to determine whether she has a masculinizing tumor. The simplest laboratory test is a determination of 17-ketosteroid excretion in the urine. If the value is within normal limits, it is probable that no masculinizing tumor is present.

REFRACTION DURING PREGNANCY

To the Editor:—Should a refraction of the eyes be postponed merely because a patient is pregnant?

Gilbert C. Norton, M.D., Endicott, N. Y.

Answer.—There are no significant ocular changes in normal pregnancy that influence errors of refraction. Refraction should not be postponed merely because a patient is pregnant.

POOR LACRIMAL DRAINAGE IN INFANT

To the Editor:—A male infant, 14 months of age, has had faulty drainage of tears in his right eye since birth. An ophthalmologist has probed his lacrimal duct twice, with apparently no results. What is recommended to correct this condition?

Abe L. Feuer, M.D., Dallas, N. C.

Answer.—A special form of lacrimal disease is occasionally seen in infants after the first few days of life. If development of the lacrimal duct is not complete at birth, the condition soon manifests itself by epiphora and slight mucopurulent discharge from the eye. The fact that the conjunctiva is not inflamed is usually sufficient to establish the diagnosis. The lacrimal sac may become distended from retention of tears and secretion, and sometimes dacryocystitis may result. The condition is often self limited, or one may relieve it by pressing the sac and forcing its contents into the nose, thus establishing the patency of the duct. This type of obstruction, which is an epithelial plug or membrane, does not tend to reform. If this method is not successful, syringing the passages or passing a lacrimal probe will usually relieve it. Frequently only one probing is required but several probings may be necessary.

FATIGABILITY

To the Editor:—A white man, aged 48, has a low systolic blood pressure, namely, 90/65. He has no complaint except fatigability. The blood pressure several years ago was 110/70. He has been taking 5 mg. of d-amphetamine sulfate in the morning and at noon without any effect on the blood pressure. What else would you recommend? Laboratory tests revealed no abnormalities.

M.D., Wisconsin.

Answer.—This patient is fortunate. With blood pressure at such a level his statistical chances of outliving those with pressures slightly above average normal are good. His fatigability is almost surely not due to the height of the arterial pressure and probably indicates that the patient requires more frequent, if less prolonged, periods of rest. No medication is required, but the patient must be convinced of his superior rather than inferior vascular status.

WHITE FINGER NAILS SINCE BIRTH

To the Editor:—The nails of an 18 year old girl have been white on the tip end (the protruding portion) since birth. Can you explain this?

M.D., Kentucky.

Answer.—The young woman apparently has leukonychia. This condition appears most often in one or more nails in the form of white punctate or transverse striae, but occasionally the entire nail may be involved or a portion of it, and the involvement may be symmetric or asymetric. Usually the finger nails are affected, but the condition has been observed also in the toe nails. The whiteness is likely due to imperfectly cornified cells with the presence of granules of keratohyalin, due to a functional disturbance of the ungueal matrix, trophic disturbances or even trauma. Trauma, as from manicuring, is frequently blamed for leukonychia, but congenital-familial cases have been observed. In many cases the cause remains unknown.

ODOR OF URINE AFTER EATING ASPARAGUS

To the Editor:—Eating of asparagus seems to be followed by the excretion of malodorous urine. What causes this odor? Some have said that asparagus "purifies" the kidneys. I cannot understand such reasoning.

Irving I. Crouse, M.D., Buffalo.

Answer.—The odor which appears in the urine after the ingestion of asparagus is due to the volatile sulfur compound methylmercaptan, which is formed as a breakdown product of the asparagin found in asparagus. This odor may persist for 12 to 20 hours and has been mainly responsible for the belief in the diuretic properties of asparagus. However, there is at present no sufficient reason for the belief that asparagus is of value in practical medicine. Because of its purin content, it is especially contraindicated for patients with gout.

LOW DIASTOLIC PRESSURE IN YOUNG PATIENTS

To the Editor:—In Queries and Minor Notes in *The Journal* of Oct. 7, 1950 (page 512) the cause of very low or zero diastolic pressure is discussed. I should like to add a point that may explain many of such readings. While one is listening for the disappearance or change of the systolic sound while the pressure cuff is being deflated, pressure with the bell or diaphragm of the stethoscope over the brachial artery will often cause a partial occlusion of the blood vessel. This has the same effect as a partially inflated cuff. One will then hear the pulsation of the blood even when the air cuff is completely deflated. This is particularly true in young persons or those with elastic arterial walls. Therefore, when one obtains a very low diastolic reading, merely easing up on the pressure with which the stethoscope is applied to the artery will result in complete disappearance of a "low diastolic pressure."

NEUROLOGIC MANIFESTATIONS ASSOCIATED WITH DISSECTING ANEURYSM OF THE AORTA

Chairman's Address

FREDERICK P. MOERSCH, M D.
and
GEORGE P. SAYRE, M D.
Rochester, Minn

The historical development of present knowledge concerning dissecting aneurysm of the aorta is a fascinating tale dating back to the sixteenth century. Familiar personages from the pages of history add color to the story. Vesalius,[1] Morgagni,[2] Nicholls,[3] Laennec,[4] Pennock,[5] Peacock,[6] Cruveilhier,[7] Sainet,[8] Swaine and Latham[9] and others have left their lasting imprint on this interesting saga. That the affliction maimed not only the plebeian but the monarch may well have aroused more than passing interest in the early study of the problem. Thus, Nicholls[3] in 1761, reporting before the Royal Society of London on the death of King George II, gave "a minute detail of what occurred on that remarkable and melancholy occasion." Nicholls went on to say, "His Majesty was found fallen on the ground, speechless and motionless He appeared to have just come from his necessary stool " At necropsy a dissecting aneurysm was demonstrated in the aortic arch.

That the clinical diagnosis of dissecting aneurysm of the aorta was of an elusive nature is given weight by quoting from Peacock,[6] who stated in 1843: "Nor are the symptoms which attend its formation and progress such as can be regarded as characteristic of the affection." If history is correct, the first antemortem diagnosis of dissecting aneurysm of the aorta recorded in literature was made by Swaine and Latham[9] in 1855.

Nearly another century had passed when Shennan,[1] in 1934, in a monumental work painstakingly analyzed the then recorded cases to the number of 300. His scholarly work summarized the known pertinent facts concerning dissecting aneurysms of the aorta. Interestingly enough, as late as 1908, Osler[10] stated that only two cases of dissecting aneurysm of the aorta had been observed at the Johns Hopkins Hospital in the preceding 16 years. Progress, however, was in the making. By 1944 Weisman and Adams,[11] in a review of 38 cases observed in the preceding 10 year period, reported that a correct diagnosis was made in 55 per cent of the cases and in 80 per cent of those in which there were associated neurologic findings The phenomenal record of correct antemortem diagnosis in 10 of 12 cases as reported by Logue[12] in 1943 is a goal that will be difficult to surpass.

It is not entirely clear to whom the credit belongs for being the first to call attention to the neurologic manifestations associated with dissecting aneurysm of the aorta. In some of the early reported cases in the literature reference is made to signs that undoubtedly indicate involvement of the nervous system Among such reports are those of Sainet[8] in 1851, Swaine and Latham[9] in 1856 and Coleman[13] in 1898, Swaine and Latham and Coleman observing signs of paraplegia in their patients. In spite of these and other reports, Kalischer[14] in 1914 is credited with being the first to emphasize the importance of neurologic complications associated with dissecting aneurysm of the aorta. It is of interest that Oppenheim, in discussing Kalischer's presentation, stated that he had never observed a similar case.

No longer may we look on dissecting aneurysm of the aorta as a rare affliction. It seems a fair statement to say that about one of every 400 to 500 postmortem examinations reveals such a pathologic process. Males are more frequently affected than females, the ratio being from 2 to 3 males to 1 female. The fifth and sixth decades of life appear to be especially vulnerable, though no decade of life is entirely exempt from the affliction. There may be sudden or rapid death from

the disease or survival for weeks, months or, in rare instances, years. According to Schnitker and Bayer,[15] the younger age group tends to have a longer duration of the illness. It is generally reported in the literature that 80 per cent of the patients die within a few days and from 80 to 85 per cent succumb within the first two weeks.

TABLE 1—*General Points of Interest*

Sex	Men, 18; women, 8, total: 26					
Age, yr.	Range 30 to 72; average, men, 56.4; women, 51.1					
Decade	4th 3	5th 6	6th 10	7th 4	8th 3	
Duration of illness	Sudden, ½ hour or less 8	One hour to several hours 1	Days 1-7 9	Weeks 2-4 4	Months 2-7 2	Years 2-8 2
Etiology	No single cause	Physical strain: 5; emotional strain: 2				
Previous hypertension	16 patients known hypertension 9 patients presumable hypertension (enlarged heart at necropsy), 1 patient normal blood pressure					

The etiology of the disease, according to the great majority of writers, including Kirkpatrick,[16] Holland and Bayley[17] and others, remains a matter of conjecture. Among the more commonly accepted causes are (1) degenerative changes in the wall of the aorta, (2) congenital defects, (3) mechanical causes, (4) inflammatory reactions and (5) trauma. As stated by Bauersfeld[18] and others, "no single cause can be demonstrated as consistently producing the changes leading to a dissecting aneurysm." According to Schnitker and Bayer,[15] pregnancy appears to play some role in the causation of dissecting aneurysm.

Death in the majority of patients (80 to 90 per cent) is due to an external rupture into one of the body cavities, in order of frequency the pericardial, the thoracic and lastly the abdominal cavity. Ten to 20 per cent of the subjects survive the initial dissection, one half of whom die later from an external rupture. However, as Osler[10] has so well stated, "in a few cases recovery takes place with an illustration of the most remarkable reparative process seen in the human body, the formation of a healed dissecting aneurysm," or, as it is frequently referred to, a "double-barreled aorta."

The diagnosis of dissecting aneurysm of the aorta remains a challenge to the physician. Each patient presents a difficult diagnostic problem, and unless a keen awareness of the symptomatology is entertained, the diagnosis may be overlooked. Under the heading of differential diagnosis, the following conditions come up time and again as important points for consideration: acute cardiac disease, acute cerebral vascular conditions, acute abdominal diseases, acute thoracic or pulmonary diseases, acute affections of the spinal cord such as abscess, hemorrhage, myelitis and finally acute arterial occlusive conditions. It should be kept in mind that occasionally the clinical picture is such that abdominal exploration is carried out because of a mistaken diagnosis. Shennan[1] and Packard and Scott[19] have reported such instances of abdominal exploration.

The clinical picture common to dissecting aneurysm of the aorta is usually of a catastrophic nature. Morgagni,[2] some 200 years ago, emphasized this point in reporting a case: "A woman, of a fat habit of body, of 50 years of age, of a sober disposition, and naturally rather inclined to sadness and taciturnity; . . . being subject to no disease, . . . having risen early in the morning to her work, . . . cried out, 'Oh!' and spoke not another word, but died instantly." In a few instances the affliction may exist unrecognized during life, coming to light only at necropsy. Most authors, such as Shennan,[1] Schlachman,[20] Gager[21] and others, agree that as a rule the dissection of the aorta is ushered in as an acute dramatic episode in which there is sudden violent pain in the chest, back or abdomen with a feeling of impending death or annihilation. The pains tend to migrate in steplike fashion from one region of the body to another, suggesting the course of progression of the dissection. It may be stated that such pains occurring in a middle-aged person with a history of previous hypertension point the finger of suspicion to the presence of a dissecting aneurysm of the aorta. In contrast to what occurs in coronary disease, pains are not frequently experienced in the arms but pains and paresthesia are common in the lower limbs.

The remainder of the clinical picture depends on the nature and extent of the dissection. Among the more important physical signs that are of aid in the diagnosis are the maintenance of a previous high blood pressure in the face of a serious vascular disturbance. The leukocyte count is usually elevated in spite of a normal or only slightly altered temperature, except as a terminal event. Examination of the heart may give but little helpful information. The presence of a cardiac murmur and the appearance of a precordial rub during the course of the illness are of diagnostic importance. The electrocardiogram may show evidence of ventricular strain or other changes, which, however, are not of a specific pattern common to dissecting aneurysm of the aorta. Roentgenographic examination of the chest may reveal helpful information and may even establish the diagnosis. Occlusion of an artery to one of the extremities should not be overlooked. Finally, the presence of neurologic signs is important in establishing the diagnosis.

TABLE 2—*General Medical Findings*

Type of Examination	Cases	Results of Examination
Temperature	14	Usually no elevation of temperature, occasionally high terminal temperature
Leukocyte count	13	Range, 6,800 to 63,000 per cubic millimeter of blood Average, 18,000
Sedimentation rate .... (Westergren)	9	Range, 17 to 138 mm. in one hour Average, 83
Urine examination	12	Albumin, grade 1 to 4 Occasionally red blood cells and casts
Urea	10	Range, 44 to 400 mg. per 100 cc. of blood Average, 106
Examination of heart	13	7 murmur, 3 no murmur, 3 no comment 2 transitory rub
Electrocardiogram ...	13	No specific diagnostic sign
Roentgen examination of chest	16	15 enlarged heart and tortuous aorta, in 4 cases suggested dissecting aneurysm
Examination of fundi	8	6 grade 1 to grade 4 hypertensive changes, 2 with edema, 2 normal
Peripheral vessels	3	2 normal, 1 no pulsation in femoral arteries

ANALYSIS OF MATERIAL

Our study consisted in an analysis of data on 26 cases of verified dissecting aneurysm of the aorta taken from the files of the Section on Pathologic Anatomy of the Mayo Clinic for the years 1924 through 1949. Twenty-two of these cases (1924 to 1948) have been previously studied by Kirkpatrick[16] from the general medical standpoint and for the pathologic nature of the aortic lesions.

TABLE 3.—*Diagnosis in 26 Cases of Dissecting Aneurysm of the Aorta*

	Admission Diagnosis	Final Diagnosis Unchanged	Correct or Suspected Diagnosis
Cerebral vascular accident (stroke)...	6	5	1
Coronary thrombosis (myocardial infarction)	7	4	3
Acute abdominal disease (gallbladder, mesenteric thrombosis, acute pancreatitis)	6	3	3
Hypertensive encephalopathy (uremia, cardiac failure)..........	3	2	1
Found dead (no clinical information)	2	2	..
Acute transverse myelitis (dissecting aneurysm of aorta)..........	1	0	1
Postoperative debility (secondary to cancer of bowel)..........	1	1	0
	26	17	9*

* In 4 cases a positive diagnosis was made; in 5 cases the diagnosis was strongly suggested.

Table 1 gives the sex, age, duration of the illness, etiologic factors and frequency of hypertension in the 26 patients. No single cause could be determined for the affection. In five patients moderate physical exertion was present at the onset of symptoms, while in two other patients considerable emotional strain was present at the time the symptoms of dissection developed. A history of previous hypertension was noted in 16 cases, the hypertension having existed for at least 10 years in six cases. In only one patient, a woman of 35 years of age with Marfan's syndrome, was it known that hypertension had not previously existed. In another patient (case 4) the history indicated an absence of previous hypertension, but necropsy gave every evidence of long-standing hypertension. In the remaining eight patients there was no information available regarding previous blood pressure readings; however, at necropsy cardiac hypertrophy was present, suggesting a previous hypertension. Table 2 outlines the pertinent physical findings in our cases. In table 3 are recorded the admission and the final diagnosis.

In 25 of the 26 patients the onset of symptoms due to the dissecting aneurysm was sudden. In only one patient was there no history or signs to indicate the time of onset of the dissection. Pain was the most constant and dramatic symptom encountered in the series of cases. Seventeen of the 26 patients experienced acute violent pain as the initial symptom. Of the remaining nine patients, five died so suddenly that no history regarding pain was obtainable. The location of the pain which ushered in the symptoms of the dissection in the 17 patients was as follows: sternal, precordial or anterior thoracic regions, 11 patients; upper abdominal area, 3 patients; upper part of the back, 2 patients, and left shoulder, 1 patient. The initial pain tended to spread over the area of onset and extend or migrate to adjoining areas. In only one instance did we note extension of pain down an arm. Frequently the pain would spread or move from chest to back or from abdomen to back and then down one or both lower limbs. These early pains, while having certain neurologic implications, are probably best considered under the heading of general symptoms. During the course of the dissection, pains of various types may be complained of, but their interpretation as to exact origin is not always an easy matter.

NEUROLOGIC COMPLICATIONS

The neurologic complications associated with dissecting aneurysm of the aorta, as may well be surmised from a knowledge of the underlying pathologic changes, are exceedingly variable and at times difficult of interpretation. Brain, spinal cord or peripheral nerves may be embraced in the pathologic process. From 11 (Shennan[1]) to 29 per cent (Weisman and Adams[11]) of the patients with dissecting aneurysm of the aorta are said to have some neurologic symptoms during the course of the affliction. In our series of cases, 12 patients (46 per cent) showed some evidence of neurologic complication. The remaining 14 patients had to be classed as having no objective neurologic findings. Of these 14 patients, nine died so speedily that no thorough examination was possible, although for four of the nine a history of pain at the onset of symptoms was obtained. In two additional patients the medical aspect of the patients' illness was of such major importance that no neurologic examination had been deemed indicated. These figures do not include terminal coma occurring in four patients who had no objective neurologic findings. Thus, the figure of 46 per cent of patients with evidence of neurologic complication might have been increased if adequate facilities for neurologic study had been available.

In the classification of the neurologic symptoms associated with dissecting aneurysm of the aorta, we attempted to follow that employed by Weisman and Adams[11] of (1) ischemic necrosis of the brain, (2) ischemic necrosis of the spinal cord and (3) ischemic necrosis of the peripheral nerves. This was not a simple matter, for in certain instances, because of the limited neurologic examination, it was difficult to be certain if the presenting symptoms were of cerebral, spinal or peripheral origin. It must also be emphasized that at times neurologic findings occurring during the course of the illness (case 3) were unrelated to the dissection but secondary to the patient's general medical condition. Table 4 classifies the major neurologic complications as they appeared in our 12 patients. In eight patients the neurologic symptoms were primarily of cerebral origin, in three patients of spinal cord origin and in one patient it was difficult to determine if the clinical findings represented cerebral or spinal cord damage. In no case could we demonstrate any objective clinical

TABLE 4.—*Neurologic Findings in 12 Cases**

	Frequency
Cerebral: 8 patients	
Hemiplegia, severe (not due to dissection in 2)..........	3
Hemiplegia, partial..........	2
Convulsions (all had other neurologic signs)..........	4
Periods of unconsciousness (3 with neurologic signs) (confusion, collapse, stupor; no terminal coma)..........	4
Probably cerebral (vertigo, facial weakness, paresthesia).....	2
Spinal cord: 3 patients	
Transverse myelitis..........	1
Probably spinal cord (weak legs, reflex changes)..........	2
Cerebral or spinal cord or both: 1 patient (pains, paresthesias of leg, confusion)..........	1
Patients with multiple neurologic findings..........	8

* Of the total 26 patients, 17 had pain as the initial symptom.

evidence of involvement of the peripheral nerves. It should be added that eight of the 12 patients had multiple neurologic findings. These figures do not include the terminal comas.

While pain was the usual signal ushering in the train of symptoms, other equally dramatic warnings gave notice of the impending disaster. Thus, the initial symptom or symptoms were pain and unconsciousness in two patients, pain and convulsions in three patients, hemiplegia in two patients and vertigo in one patient.

As noted in table 4, the major number of neurologic complications were of cerebral origin. Five patients had definite signs of hemiplegia. Three of these had marked weakness of the affected side (unrelated to the dissection in two), and two had moderate weakness of the palsied side. In three of the five patients the weakness involved the left side and in one the right side, and in one the side affected was not recorded. Hemiplegia may occur as an initial symptom, or it may develop during the course of the illness. It is well to bear in mind that not every hemiplegia occurring during the course of the illness need be due directly to the dissection but that hemiplegia may result from other unrelated factors.

REPORT OF ILLUSTRATIVE CASES

Case 1 illustrates one of the commoner types of clinical histories of a dissecting aneurysm of the aorta.

Case 1.—The patient was a man who had been in good health up to 46 years of age, at which time hypertension was first noted. On May 3 of his fifty-second year he awakened at 6:15 a. m. with a severe, sharp pain in his back which extended around over his abdomen. Thirty minutes after the onset of pain he noted numbness and tingling in his left leg. Tenesmus developed, and he began passing large amounts of flatus, with liquid projectile bowel movement. His blood pressure was 290 mm. of mercury systolic and 140 diastolic. He was given a hypodermic injection of ¼ grain (0.016 Gm.) of morphine sulfate, which did not relieve the pain. At 8:45 a. m he attempted to go to the bathroom but had to be carried back to bed as he collapsed, became cyanotic and ceased to breathe.

At necropsy the pericardial sac was distended by 750 cc. of blood. This blood came from an adventitial tear of the intrapericardial portion of the ascending aorta which communicated with a dissecting aneurysm. The internal tear to the dissecting aneurysm was at the origin of the left subclavian artery. The dissection extended along the inferior surface of the arch of the aorta to the tear in the pericardium but did not involve the other major branches in the neck. It also extended distally along the posterior surface of the aorta, into each iliac artery. In the course of the dissection the left subclavian artery was partially compressed at its origin, and all the intercostal and lumbar arteries were torn.

The brain and the spinal cord appeared essentially normal on gross examination. Histologic examination of the brain revealed marked arteriolosclerosis. Sections of the medulla and of the cervical portion of the spinal cord showed, in addition, congestion of the vessels. In the midthoracic region there were multiple perivascular hemorrhages in both the gray and the white matter. In the lumbar and sacral portions of the spinal cord similar but fewer hemorrhages were present.

Convulsions, loss of consciousness and periods of confusion are fairly frequent manifestations of cerebral involvement. Such symptoms may or may not be associated with objective neurologic findings. Case 2 is an example of a patient having convulsions and objective neurologic findings. This case also demonstrates the importance of obtaining roentgenograms of the chest to visualize abnormal changes in the aorta.

Case 2.—The patient, a man 39 years of age, was seized with a sudden severe interscapular pain followed at once by nausea and vomiting. The pain "shot" through his entire chest, lasting a few moments but followed by a persistent ache. The following evening he had another episode of severe pain in his chest, which was followed by two generalized convulsive seizures and semistupor which lasted for about one hour. In the succeeding days he continued having some pain in his chest but had more constant and severe pain over his abdomen and the lumbar portion of the spinal column requiring codeine for relief.

The temperature was normal. The blood pressure was 230 mm. of mercury systolic and 168 diastolic. The leukocyte count was 14,100 per cubic millimeter of blood. Albuminuria was graded 3. The blood urea level was 70 mg. per 100 cc. The sedimentation rate was 74 mm. per hour (Westergren). There was no cardiac murmur, but the electrocardiogram showed a ventricular strain pattern. Roentgen examination of the chest demonstrated an aneurysmal dilatation of the ascending, transverse and descending aorta. The neurologic examination revealed all the deep reflexes in the lower limbs to be decreased and bilateral Babinski reflexes to be present. There was generalized weakness but no paralysis.

The pains gradually lessened. On the evening of the fifteenth day the patient suddenly became apprehensive, dyspnea developed, and he sank into unconsciousness and died in a few minutes.

At necropsy, a dissecting aneurysm was observed to extend from the left common carotid artery to the left iliac artery. The left common carotid artery was compressed at its origin, while the left subclavian artery was narrowed and dissected. All the thoracic and upper abdominal intercostal arteries were torn. The lower abdominal intercostal arteries were intact. The dissecting aneurysm reruptured into the left common iliac artery. There was an external tear into the left pleural cavity, which contained 1,500 cc. of blood. The cerebral convolutions were moderately flattened. On coronal section of the brain the surfaces were unusually moist.

Histologic examination revealed a diffuse sclerosis of the cerebral arterioles, with pyknosis of many nerve cells and with swelling of the oligodendroglia and loosening of the ground substance in the adjacent white matter. In the pons and medulla there were numerous irregularly distributed arterioles containing thrombi with greater and lesser perivascular areas of hemorrhage and infarction. Sections of the spinal cord were essentially normal.

As we have mentioned, not all neurologic symptoms developing during the course of illness in cases of dissecting aneurysm of the aorta need result directly from the dissection. Case 3 is an example of a hemiplegia occurring during such an illness as an unrelated symptom.

Case 3.—The patient, a man 60 years of age, was known to have had hypertension for eight years. Three years before his admission to the clinic he had had what was thought to be partial occlusion of the right posterior-inferior cerebellar artery. At the time roentgenographic examination of the chest had revealed a tortuous aorta with slight calcification.

At 60 years of age, while mixing cement, he was seized with sudden severe pain in his abdomen which extended to his back. Lying down was painful, but he obtained some relief by being up and walking. Systolic blood pressure was 260 and diastolic 140 mm. of mercury. The leukocyte count was 16,000 per cubic millimeter of blood. The electrocardiogram indicated left ventricular strain. A tentative diagnosis of coronary occlusion was made, though the possibility of mesenteric thrombosis was entertained. In about 48 hours the pain subsided. Twenty-three days after the initial pain he arose, ate breakfast and lay down on his bed. An hour later his wife found him with complete flaccid paralysis of the left side. He was confused, gradually sank into a coma and died within 12 hours.

At necropsy there was a dissecting aneurysm extending from the junction of the arch and thoracic aorta to the first portion of the left iliac artery. The major vessels of the arch were not involved in the dissection. The proximal rupture was at the junction of the upper and middle thirds of the thoracic aorta, with a reentrance tear through the left iliac artery. The dissection tore the left intercostal arteries and some of the upper lumbar arteries. Examination of the brain showed the right hemisphere to be swollen and on section to contain a large hemorrhage in the right external capsule which had ruptured into the right lateral ventricle. The spinal cord was not examined.

It was rather surprising, after viewing the pathologic specimen of a dissecting aneurysm of the aorta with the torn intercostal and lumbar vessels, to find that there were so few complications involving the spinal cord. Three of our patients exhibited symptoms that we ascribed to damage to the spinal cord. Such neurologic findings consisted in weakness of one or both legs, paresthesias, pains and reflex changes. Case 4 is an example of irreparable damage to the spinal cord; Weisman and Adams[11] and more recently Scott and Sancetta[22] have described similar cases.

Case 4.—The patient was a man 59 years of age. On Oct. 27, 1948, on arising in the morning he had a sudden, severe, sharp pain in the upper part of the sternum that took his breath away. He got up to get a drink of water but returned to bed, since the pain became severer. It extended down the sternum and then through to the back. It was excruciating, and the patient became dyspneic. In about ten minutes the pain lessened, and it was then noted that his legs were rapidly becoming numb and weak, the numbness spreading upward to the level of the umbilicus. During the following days the pain in the chest and back recurred off and on in milder degree but required morphine sulfate for relief.

On the third day the patient was admitted to the hospital. Neurologic examination revealed flaccid paralysis of the lower limbs. There was a complete loss of sensation to the level of the umbilicus, with absent deep reflexes and absent plantar response. The spinal fluid was normal. Physical examination showed normal temperature, the blood pressure was 100 mm. of mercury systolic and 30 diastolic, the leukocyte count was 13,100 per cubic millimeter of blood and the sedimentation rate was 70 mm. per hour (Westergren). Roentgenographic examination of the chest showed a tortuous aorta, with cardiac enlargement. An aortic systolic murmur was present with a transitory pericardial rub. The electrocardiogram showed some evidence of ventricular strain but was not diagnostic.

The patient's pain subsided entirely during the following four days. He was dismissed from the hospital on Nov. 19, 1948, with no change in the neurologic condition. A diagnosis of dissecting aneurysm of the aorta was made During the following months he had recurring infections of the bladder and increasing decubital ulcers. He died on May 10, 1949, six and one-half months after the initial symptoms.

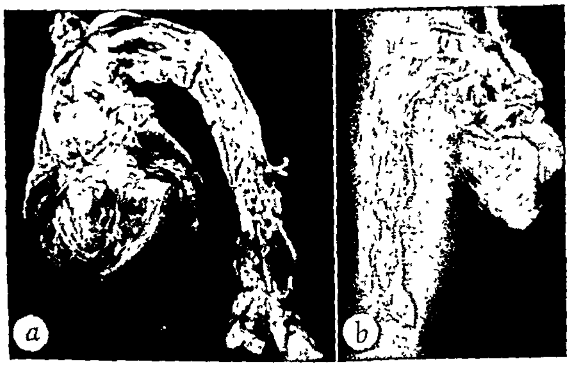

Fig. 1 (case 4).—The aortic luminal side (*a*) and the dissecting aneurysm (*b*). Note the opening in the intima in the ascending aorta and the stretched and torn intercostal vessels with wide open lumens.

At necropsy the heart weighed 800 Gm. and was symmetrically enlarged. On the aortic valve were four recent friable vegetations, the largest 1.2 cm. in diameter. The aorta consisted of a tube with a double lumen, the posterior lumen being a dissecting aneurysm extending from the root of the aorta to the iliac arteries (fig. 1). There were four intimal tears of the ascending aorta opening into this aneurysm; two of the tears had vegetations similar to those on the aortic valve. There was a reentrance tear in the left iliac artery. The dissection extended up the subclavian and common carotid arteries on the right. A few right intercostal arteries were stretched across the lumen in the thoracic aorta, but the remaining intercostal and all the lumbar arteries were severed. The openings of these vessels were patent, however.

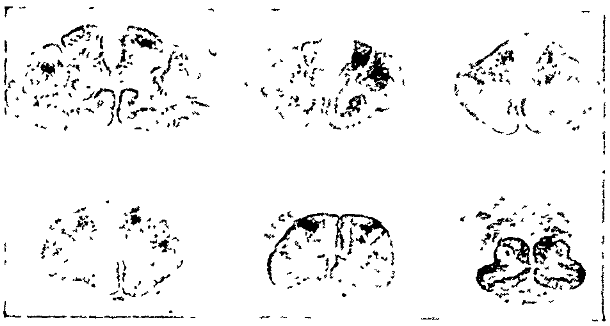

Fig. 2 (case 4).—Weigert-stained sections of the spinal cord showing the degeneration of the ascending tract in the cervical and upper thoracic regions, beginning degeneration of the gray matter in the midthoracic region and extensive loss of gray matter in the low thoracic, lumbar and sacral portions of the spinal cord, with partial preservation of the posterior tracts.

The brain revealed an old infarct in the right superior lobe of the cerebellum. The spinal cord had a normal, firm consistency to approximately the level of the seventh thoracic vertebra. Distally it was shrunken and soft, without the normal lumbar enlargement. On section of the cervical and upper thoracic segments, the posterior columns were white and glistening. The midthoracic segment of the cord was softer, particularly the central gray matter, while in the lower thoracic, lumbar and sacral regions the gray matter was replaced by an irregular honeycombed yellowish cavity.

Histologic examination of the spinal cord (fig. 2) showed that in the cervical region the normal architecture was preserved. There were, however, a considerable decrease in the size of the fasciculus gracilis and a loose appearance of the dorsal and ventral spinocerebellar and spinothalamic tracts, with loss of myelin. Sections of the upper thoracic region were similar, but the loss of myelin was more marked. In the midthoracic region the intramedullary blood vessels were patent. The degeneration of the ascending tract was more pronounced. In the gray matter the neurons of the posterior portion of the anterior horns were missing. In sections at the lower thoracic, lumbar and sacral regions there was a complete loss of the normal central gray matter, and all the nerve cells were missing. The normal tissue was replaced by a fine lattice work of glial fibers with a few swollen astrocytes and many fat-laden macrophages in the meshes. The intramedullary blood vessels remained patent. There was loss of myelin in the ascending tracts, with preservation of myelin in the descending tracts. The axis cylinders were frequently fragmented and swollen. The anterior roots were demyelinated, while the posterior roots maintained the myelin.[22a]

Other striking neurologic conditions, such as aphasia, blindness and changes in the sympathetic nervous system, have been described as occurring in association with dissecting aneurysm of the aorta. As a rule such changes may readily be explained when viewed with the pathologic findings in mind.

CLINICAL AND PATHOLOGIC CORRELATION

There were available for this study the dissected aortas in the 26 cases. In addition we had the brains in 12, the spinal cords in nine and portions of the sciatic nerves in nine cases. The aortas were studied to determine the location and extent of the dissection and to correlate the involvement of the aortic branches with possible interference with the vascular supply of the central and peripheral nervous systems. To appreciate this correlation, an appraisal of the blood supply of the brain and of the spinal cord may be reviewed.

[22] Scott, R. W., and Sancetta, S. M.: Dissecting Aneurysm of Aorta With Hemorrhagic Infarction of the Spinal Cord and Complete Paraplegia, Am. Heart J. 38: 747-756 (Nov.) 1949.

[22a] Through the courtesy of Dr. W. E. Youland, pathologist, Cherokee State Hospital, Cherokee, Iowa, we have learned that the brother of this patient also died of a ruptured dissecting aneurysm of the aorta.

The blood supply of the brain comes from two sources: the internal carotid arteries and the vertebral arteries. The spinal cord receives a more complicated blood supply. The anterior spinal artery, which supplies the major portion of the cord, is formed from the paired vessels from the vertebral arteries and the eight or nine irregularly distributed radicular arteries which are derived from the paired intercostal arteries. The parallel posterior spinal arteries, also branches of radicular arteries, supply only the superficial dorsal portion of the cord and have only very fine anastomoses with the anterior spinal arteries. These radicular branches as described by Suh and Alexander [23] are depicted in figure 3. The anterior spinal artery in the midthoracic region becomes markedly attenuated. The major blood supply of the spinal cord below this region comes from a large lower thoracic or upper lumbar vessel, named by Adamkiewicz [24] the arteria radicalis anterior magna. Experimentally, Suh and Alexander were unable to fill the vessels of the lower end of the spinal cord by injecting opaque material into the upper portion of the spinal artery above the attenuated area in the midthoracic region, although the reverse was possible. As shown in figure 3, interference with the blood supply in branches of the aorta, such as could occur with dissecting aneurysm, might well be responsible for pathologic changes in the nervous system normally supplied by such vessels.

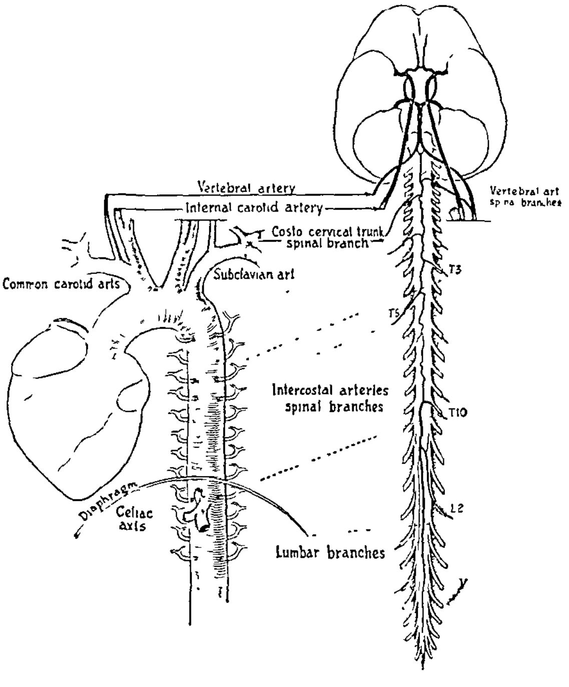

Fig. 3.—Schematic drawing of blood supply to the central nervous system, showing the relationship of the major branches of the aorta to the terminal branches supplying the brain and the spinal cord. (Redrawn in part from Suh and Alexander, *Arch. Neurol. & Psychiat.* **41**: 659-677 [April] 1939 [by permission]).

Of the 12 cases in which the brain was examined, six showed that the dissection involved the major vessels of the aortic arch, while in the other six cases no such involvement was evident. In both groups of cases the clinical and pathologic findings did not parallel one another. Thus, in some instances in spite of considerable dissection of the vessels of the aortic arch no clinical findings were present. On the other hand, in some cases clinical signs of cerebral damage occurred without evidence of dissection of the vessels of the aortic arch being present (tables 5 and 6). In the 14 cases in which the brain was not examined the clinical symptoms had no constant relationship to the state of the vessels of the aortic arch. It should be remembered, however, that the dissection along a vessel does not necessarily imply obliteration of the lumen of that vessel. Furthermore, because of the double cerebral blood supply of the basilar artery and of the circle of

TABLE 5.—*Relationship of Dissection of Vessels of Aortic Arch to Cerebral Lesions and Neurologic Symptoms*

Vessels Affected	Cerebral Lesions	Neurologic Symptoms
All	None	Convulsions 3 days before death
All	Infarct of right basal ganglion	Left hemiparesis for 3 days
All	Old infarct of cerebellum	None
Left subclavian and left carotid	Multiple small infarcts of pons	Convulsions; positive Babinski sign
Left subclavian	Early thrombus of right middle cerebral artery	None; death in 3 hours
Innominate	None	Sudden death

TABLE 6.—*Relationship of Dissection of Vessels of Aortic Arch to Cerebral Lesions and Neurologic Symptoms*

Vessels Affected	Cerebral Lesions	Neurologic Symptoms
None	Massive cerebral hemorrhage	12 hours before death left hemiplegia
None	Massive cerebral hemorrhage	Sudden death at time of dissection
None	Cerebral atrophy and old infarcts	Recent dissection; patient found dead in bed
None	Old infarcts of internal capsule	Onset of dissection 3 years ago; 7 months ago "stroke"; 7 weeks ago right hemiplegia
None	Old infarcts of internal capsule and pons	Died suddenly at home
None	Cerebral edema	Convulsion

TABLE 7.—*Relationship of Dissection of Vessels of Aortic Arch and Intercostal Vessels to Lesions of Spinal Cord and Neurologic Symptoms*

Vessels of Arch	Intercostal Vessels		Lesions of Spinal Cord	Neurologic Symptoms
	Thoracic	Lumbar		
All	All	All	Infarction of lower part of cord	Paraplegia
Left subclavian	All	All	Multiple perivascular hemorrhages	Numbness and tingling of legs; death in 3 hours
None	All	All	None; arteriolosclerosis	None
Left subclavian	All	Upper	None; arteriolosclerosis	Positive Babinski sign (infarcts of pons)
None	Lower	All	None	None
None	Upper	All	None	None
None	None	Upper	Acute infarct around sclerosed vessels	None
None	None	Upper	None; arteriolosclerosis	Weakness of legs
Innominate	None	None	None	None; sudden death

Willis, interference with one or more vessels at the aortic arch might not produce cerebral lesions, except in the presence of unusual irregularities or inequalities in the circle of Willis. Finally, because of the associated hypertension, cerebral damage may antedate the dissection or occur independently of it.

In nine cases the spinal cord was examined (table 7). In two cases there were lesions due to interference with the blood supply by dissection of the majority of the intercostal arteries. The most notable changes of the spinal cord occurred in case 4. The other patient with dissection of all the intercostal vessels lived but a few hours, during which time he complained of numbness and tingling in the legs. The spinal cord showed multiple small perivascular hemorrhages. In the remaining seven patients, in whom considerable dissection of the intercostal vessels had occurred, the spinal cord revealed some evidence of arteriosclerosis but no lesions that could be attributed to interference with the blood supply resulting from the dissection; however, one of these patients had some objective evidence of damage of the spinal cord.

In 17 cases the spinal cord was not available for study. In six of these most of the intercostal vessels were torn, while in six many of these vessels were dissected. In all the 12 cases there were no major clinical signs of damage of the spinal cord The remaining five cases demonstrated no dissection of the intercostal arteries and no objective clinical findings

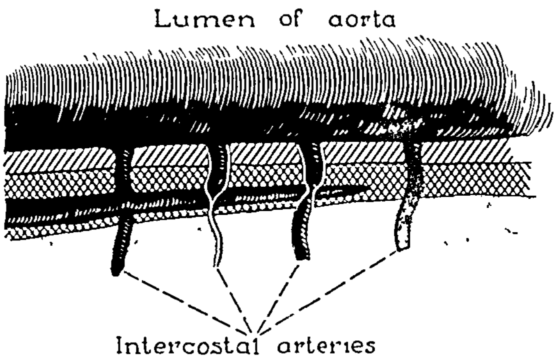

Fig 4—Schematic drawing of the mechanism of spinal ischemia in dissecting aneurysm The dissecting blood, as it extends along the media, stretches the intercostal arteries, first narrowing them and then causing complete occlusion Further stretching leads to rupture of the vessel with reopening of the lumen, which now receives its blood supply, at least in part, from the secondary lumen.

The discrepancy between the extensive tearing of the intercostal vessels and the absence of both neurologic and pathologic findings can best be explained on the basis of the mechanical effects of the dissection on the intercostal vessels (fig. 4). Gross and Hufnagel,[25] in their experimental work on coarctation of the aorta, found that in dogs obstruction of the aorta at the arch for 10 to 50 minutes might produce spinal paralysis It would, therefore, seem that, in man, if the intercostal arteries are stretched for a sufficient length of time before their rupture and the reestablishment of circulation, degenerative changes in the spinal cord might be expected. Another factor requiring consideration is the degree of arteriosclerosis of the affected intercostal vessels. Arteriosclerosis might modify the blood supply to the spinal cord prior to the dissection. It might shorten the time between the stretching and rupture of vessels, and finally it might help to prevent the collapse of the affected vessels.

Proximal portions of the sciatic nerves in nine cases appeared to be essentially normal. This does not rule out degeneration in the distal portions of the nerves, which were not available for study.

COMMENT

From an analysis of our material, certain points may be emphasized. Dissecting aneurysm of the aorta is probably of more frequent occurrence than is usually supposed. The symptoms are fairly characteristic. While much progress has been made in the antemortem diagnosis, the disease remains an elusive one. Frequently the patients are seen in emergency and in circumstances in which an accurate history is difficult to obtain, and the examination may not be satisfactory because of the critical state of the subject. Then, too, in the differential diagnosis so many serious conditions more commonly encountered in routine medical practice have to be included for consideration that the possibility of a dissecting aneurysm of the aorta may be overlooked.

The neurologic complications tend to follow definite patterns of cerebral, spinal cord or peripheral nerve origin. Frequently the neurologic symptoms may be diffuse, involving all portions of the nervous system In our series of cases 46 per cent of the patients gave evidence of neurologic complication. Involvement of the peripheral nerves was essentially negligible, though it must be pointed out that in our study only portions of the sciatic nerves were available for examination. From the clinical standpoint, one certainly gains the impression that many of the pains suffered by these victims might well be due to implication of the peripheral nerves.

The cerebral manifestations are exceedingly variable and can usually be explained on an anatomicopathologic basis. In instances in which the cerebral symptoms cannot be thus explained, they may be due to sudden changes in cerebral blood flow secondary to altered blood pressure resulting from shock and not to any mechanical obstruction in the vessels arising from the aortic arch. There does appear to be a reasonable explanation for the apparent serious disturbance of the vascular supply to the spinal cord.

The correct diagnosis of dissecting aneurysm of the aorta will depend on the physician's understanding of the underlying pathologic process and his awareness of the ensuing symptoms. From a review of our material, we found that the more important points to be considered in establishing a correct diagnosis are in accord with those outlined by Willius and Cragg,[26] and by Glendy, Castleman and White,[27] as follows: (1) the sudden onset of symptoms, with prostration or collapse; (2) the presence of severe and usually prolonged and migrating pains; (3) the presence of hypertension; (4) the presence of neurologic symptoms; (5) normal to only slightly elevated temperature; (6) an enlarged heart with a cardiac murmur and transitory pericardial rub; (7) an electrocardiogram that is not diagnostic; (8) roentgenographic findings of enlarged heart with tortuous aorta which may be dilated and calcified; (9) increased leukocyte count, and (10) albumin in the urine, at times red blood cells.

CONCLUSIONS

Dissecting aneurysm of the aorta is not so uncommon as is usually supposed. Up to the present time no single cause has been demonstrated as a basis for the affliction. As a result of an increasing awareness of the condition, the antemortem diagnosis is made more frequently and especially so if neurologic symptoms are present. In our series of cases, 46 per cent had some neurologic complications. Cerebral symptoms predominated, but dramatic spinal cord symptoms did occur. Most of the neurologic involvement could be explained on the basis of interference with the blood supply to the brain and the spinal cord. At times the symptoms were due to causes associated with the dissection but not directly related to it.

MASSIVE SEPARATION OF THE RETINA IN FULL TERM INFANTS AND JUVENILES

PARKER HEATH, M.D.
Boston

The diagnosis and classification of massive separation of the retina in infants and juveniles is a difficult clinical problem. The vitreal and postlental mass is usually considered to be of inflammatory or neoplastic origin. Depending on the considered etiological basis the condition is referred to as pseudoglioma, retinitis exudativa (Coats's disease) or malignant growth. When premature birth is part of a child's history, the retinopathy of prematurity (Terry's retrolental fibroplasia) is considered. In a study of the last-mentioned disease reported before the Section on Ophthalmology in 1949 examples were encountered of massive separation of the retina occurring in full term infants and juveniles.[1] It is this material augmented by other examples in the collection of the Eye Pathology Laboratory which is used in this report to round out a study of infant and juvenile retinal disease.

The literature of ophthalmology is confusing on the subject of massive retinal separation. References appear under various labels, such as exudative, hemorrhagic or massive retinitis, pseudoglioma, retrolental fibroplasia, Coats's disease and massive gliosis. Collins,[2] as early as 1892, reported that pseudogliomas were due to a fibrosis in the postlental area, choroidal tubercle or inflammation of the uvea and vitreous effusion. Coats's [3] paper, definitive for his time (1908), was entitled "Forms of Retinal Diseases with Massive Exudation." He classified the pathological features of his material into three groups: as an exudation (1) without exaggerated vascular disease; (2) with pronounced vascular changes, and (3) with arterial vascular communication. In a further report (1912) [4] his title was "On Retinitis Exudativa"—sometimes referred to as retinitis hemorrhagica externa. In this paper he separately designated the arteriovenous communication group as an angiomatosis of the retina. Coats's clinical observations may be summarized as follows: the patient, usually a male, of normal general health and family history showed unilaterally a whitish, yellowish exudation in the retina, accompanied with a hemorrhage and structural vascular anomalies. The process was noted to advance gradually and painlessly to complete separation of the retina. From his studies Coats reported exudation of serum and hemorrhage within and outside of the retina, and numerous macrophages accompanied with fibrosis in and between the retina and in the choroid. All these changes were described as exaggerated in late stages. Coats considered that a number of causes could produce the retinal separation.

Leber [5] in 1915 considered these pathological processes to be inflammatory and to show foci of necrosis. He ascribed the origin of a considerable number of macrophages to proliferations of the pigment layer of the retina. He thought that the retinal separation was due to serofibrinous exudation. In the late stages he noted encapsulation by fibrous tissue. Schieck [6] (1930) in Kurze's Handbuch listed published reports and describes similar stages of the pathological process. Lamb [7] in a valuable report (1938) on exudative retinitis described both early and late microscopic lesions. He found primary extensive albuminous edema in whole or part of all layers of the retina—a diffuse process. Some of his patients showed perivasculitis and macrophages, which he thought indicated inflammation. Connective tissue was noted on the inner surface of the retina. He also considered the process to be a retinitis and thought that the retinal pigment epithelium was an important factor in the secondary changes.

Marshall and Michaelson [8] (1933) reported a series with emphasis on eight characteristics: (1) youth of the patient; (2) late stage of the process when seen clinically; (3) chief pathological changes in outer layers of the retina; (4) numerous large bladder cells; (5) relatively insignificant hemorrhage; (6) lack of subretinal membrane; (7) normal pigment layer of the retina, and (8) normal choroid. They considered their cases similar to Leber's retinitis exudativa serofibrinosa. Reese [9] (1936) described three interesting cases of massive retinal fibrosis and gave some thought toward considering this reaction as an entity. Elwyn [10] (1940) described his conception of retinitis exudativa as primarily a vascular malformation with secondary changes due to transudations and hemorrhages.

If I use the loose descriptions of what constitutes these retinopathies, this communication could be said to be a report of 100 cases of pseudoglioma and 22 cases of Coats's disease. Neither term is satisfactory. However, I believe from a study of this material that it is possible to classify massive separation of the retina in infants and juveniles on the basis of a close relationship to a principal cause. Granted that a similar ocular

pathological appearance may arise from different agents and that it is often difficult to relate the initial agent to the chief destructive force—nevertheless, a careful study of the early lesions will usually indicate a cause. This is not possible in late stages because then extensive diseases of the retina resemble one another. Trauma is not considered to be a primary retinal disease and is omitted from the following suggested classification, which will be illustrated in part by brief case reports.

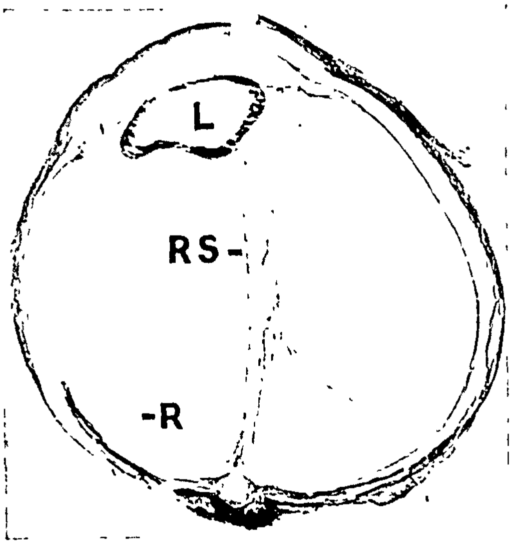

Fig. 1.—Right eye, boy aged 3½ years, illustrates massive separation of the retina, due to its incomplete differentiation, and a deficient secondary vitreous. *L*, the lens, with some posterior cataractous changes, thickened capsule; *RS*, retinal stalk forming retrolental fibrosis behind lens on temporal side, and *R*, incompletely differentiated retina.

Classification of Massive Separation of the Retina in Full Term Infants and Juveniles

Group 1.—Retinal Aplasia and Dysplasia: Due to fetal injury at 13 to 65 mm. stage, often accompanied with deficient secondary vitreous.

Group 2.—Specific Inflammation: Uveitis and endophthalmitis, arising from diverse agents, from bacterial, mycotic and parasitic infections.

Group 3.—Vascular Retinopathy: Disrupting retinal edema or hemorrhage due to pathological permeability that is nonspecific and caused by metabolic disease.

Group 4.—Primary Retinal Neoplasm Neuroectodermal (retinoblastoma), vascular (angiomatosis) and neuroglial (glioma or astrocytoma).

SHORT DESCRIPTIONS AND ILLUSTRATIONS OF THE SEVERAL TYPES OF MASSIVE SEPARATION OF THE RETINA

Group 1, retinal aplasia and dysplasia, is distinguished by congenital ocular maldevelopment, chiefly seen in these rare cases as incompleteness of retinal structure and an insufficient secondary vitreous. The membrane has not enough vitreous support on its inner surface to compel approximation against the choroid; there results loose coaptation, folds, stalks and early congenital massive separation. These patients usually have good general health but others may show dysplasia involving the central nervous system. Clinically, the process is noncongestive, unilateral and painless. Histopathologically the degree of manifestation is closely related to the level of differentiation of the retina. The affected eye is always smaller than its fellow. Some patients show a substantial retinal stalk which includes the hyaloid artery and extends anteriorly from the nerve head. There usually is a retrolental fibrous proliferation induced by the dislocated retina. In addition, the lens is usually cataractous in its posterior cortex and is intimately connected to a membrane which pulls in the ciliary processes. Characteristic findings on the inner surface of the retina are fibrous tags with brushlike terminations. An example of this group (undifferentiated retina) is as follows (figs. 1, 2, 3 and 4):

The right eye of G. W., a boy 3½ years of age, had been smaller than its fellow since birth. Measurements were 18 mm. in the horizontal diameter and 19 mm. in the anterior-posterior. The lens showed postcortical opacification, a thick capsule and a retrolental membrane on its temporal side, drawing in some ciliary processes. A stalk composed of undifferentiated retina and a functioning hyaloid artery extended from the posterior portion of the lens to the nerve head, and a fibrous band extended to the ciliary body from the back of the lens. About one half of the retina had collapsed into an axial position. On the inner surface of the retina were brushlike tufts, abortively contributing to an incompletely formed vitreous. The retina showed a pigment epithelium, partial outer granular layer and incomplete nerve fibrillary layer. The ganglion and nerve fiber layers were not differentiated. The choroid was only partially developed.

Group 2, the largest, represents specific inflammations; it includes the monocular massive separations of the retina from uveitis and endophthalmitis due to demonstrable causes. The pathological processes are suppurative and granulomatous. A careful and prolonged study of the patient and/or the specimen usually reveals one of the many possible causative agents. Meningococcic meningitis in the recent past in this country has been a common cause (about 3 per cent in some epidemics). The Cysticercus parasite in some parts of the world has long been identified as an occasional cause of uveal disease and retinal separation.

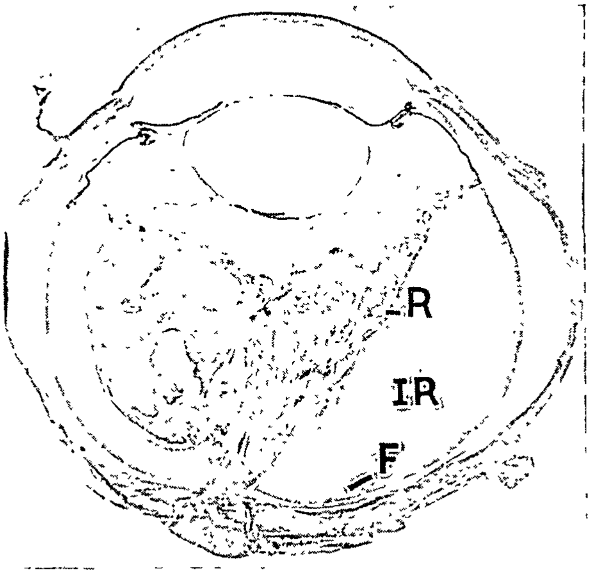

Fig. 5.—Nematode endophthalmitis: *R*, retina shows massive separation and organization and cyst formation and contains worm parasites; *IR*, intraretinal fluid; *F*, fibrosis on pigment layer of retina and choroid.

Of considerable importance, and up to now not emphasized in this country, are the massive separations associated with an endophthalmitis due to mycotic infection and worm parasites. The latter were described by Wilder[11] in a preliminary report at the 1950 Pan-American Congress of Ophthalmology. The parasites (often nematodes) were only found after much search-ing through many sections. It is probable that it will take considerable time to establish the ocular incidence of various parasitic infections in this country. Sections of early lesions more readily show identifiable fungi and worm parasites. *In either case the tissue often responds* by an increase of eosinophilic cells and sometimes by a sharp increase of multinucleated plasma cells Numerous histiocytes are usually to be found along the choroidal and retinal borders of the intraretinal fluid and within the retina. Edema is excessive and some hemorrhage is present. In early cases of each infection, various cycles of the parasite are sometimes found in the choroid, vitreous and retina, especially along borders of the intraretinal fluid and in the retrolental region. A pertinent point is that edema and hemorrhage force the retina apart. It usually is not pulled off by secondary vitreous organization. In late stages fibrosis and pathological repair mask evidences of the invasion The site of the parasite may sometimes be identified by an accumulation of inflammatory cells about a remnant. Contaminants, especially fungi, are liable to be present. It would be ideal to be able to classify pathogens from cultures. The accurate classification of species, especially fungi, depends on cultural characteristics. The pathologist ordinarily does not obtain the specimen in a fresh state, but culture and animal inoculations should be done from suspected material whenever possible. The vectors of these invaders are still to be discovered. The family pet is a likely source of nematodes. The *following is an example of massive separation of the* retina due to nematoid endophthalmitis:

---

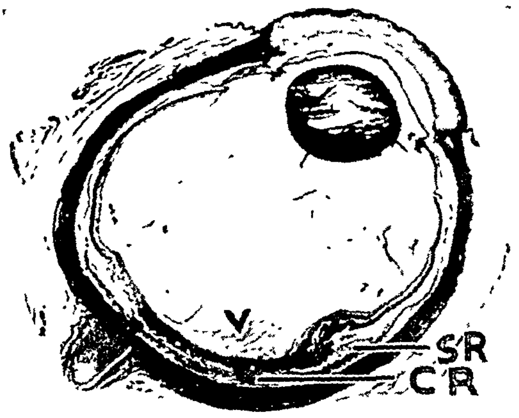

Fig 11—Cryptococcus neoformans (Torula) endophthalmitis There is an extensive necrotizing congenital chorioretinitis with massive separation, part of a general infection, maternal in origin *V*, protein rich fibrinous vitreous, *SR*, serum under necrotic retina, and *CR* chorioretinitis

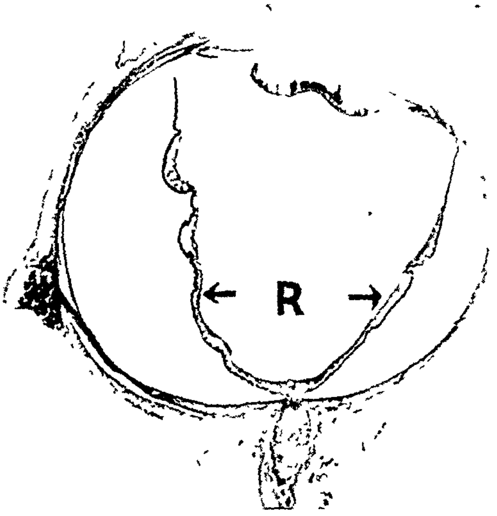

Fig 15—Massive splitting and separation of the retina, *R*, in an early state, due to hemorrhage

After a mild attack of measles a child 2½ years of age showed in the right eye a whitish pupillary reflex two months before admission. The iris was muddy and greenish in appearance compared with the unaffected left eye When the eye was opened in the laboratory, the retina was separated and balled behind the lens. Microscopically the iris showed diffuse infiltration with lymphocytes, plasma cells, some multinucleated, and a few macrophages. Eosinophilia was pronounced. Posterior synechiae were present. A thick fibrous retrolental membrane was associated with the balled retina. Fibrous inflammatory and cystic bands extended into the intraretinal fluid.

The ciliary processes were drawn inward. The retina was attached at the ora serrata, where there was some pigment proliferation and clumping, and at the dragged-in nerve head It showed pronounced folding and dissociation from edema, numerous collections of histiocytes, cyst formation and gliosis Heavy focal accumulations of lymphocytes were scattered in the retina and occasionally in the ciliary body. The choroid was edematous. On the pigment epithelial surface of the separated retina were nodules of fibrin representing organization of repair of hemorrhage Some early atrophic changes were noted in the optic nerve. In sections parasitic worms were found in the anterior vitreous, and some were cut in different planes, and apparently in different cycles, in the retinal fluid and its organizing membrane The whole process was subacute. Secondary walling off and fibrin were moderately present The case is illustrated by figures 5 to 10, inclusive.

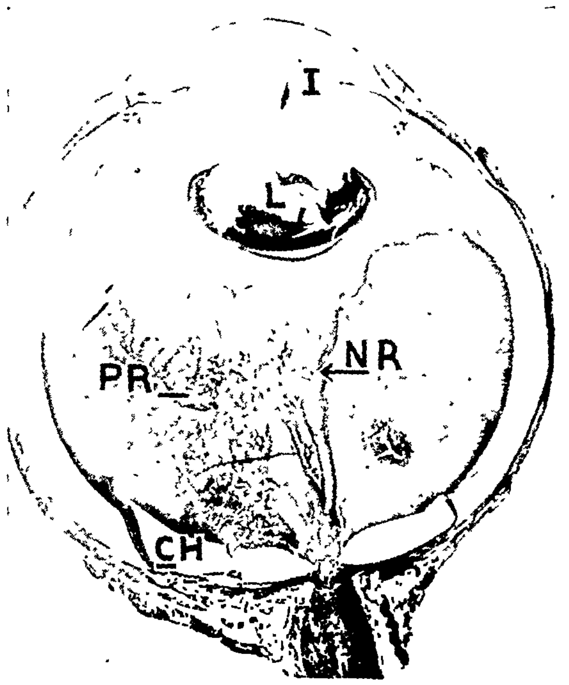

Fig 25—Massive separation of retina due to angiomatosis is representative of primary tumor *I*, iris, anterior synechia, *L*, lens, *NR*, norma leaf of retina separated by protein rich serum, *PR*, neoplastic proliferating vascular tissue within the retina, and *CH*, choroid artefactually separated from sclera

It is possible for a child to be born full term with a mycotic infection of maternal origin. An example of this is endophthalmia from Torula. Infant toxo*plasmosis which also is maternal in origin does* not separate the retina, in my experience, because the necrotizing process is focal in both retina and choroid and fuses these structures.[12] The possibility exists of a combined lesion, and this subject is not closed at this time. The following is an example of bilateral endophthalmitis due to a fungus, maternal in origin, and showing massive separation:

A male infant, about a month premature, at the time of death (27 days) showed a generalized infection from Cryptococcus neoformans; many organs were involved. *Culture* was positive. Some pathological changes suggested a dual infection of cryptococcosis and toxoplasmosis. Ocular sections showed a diffuse, necrotizing chorioretinitis with pronounced dissociation of tissue elements unlike the typical focal chorioretinitis of toxoplasmosis; the vitreous contained fibrin. The retina showed extensive separation with considerable phagocytosis of retinal pigment. Cryptococcus neoformans organisms were easily found in the retina and brain (figs. 11-14).

Group 3, vascular retinopathy, includes nonspecific vascular disease of the retina manifested by pathological permeability. Separation of the retina is brought about by excessive edema and hemorrhage. A possible variant is characterized by multiple primary retinal cysts; it is so rare and its underlying cause so obscure that its inclusion in group 3 is tentative. These binocular manifestations, whether from edema, hemorrhage or multiple cysts, apparently are spontaneous and unaccompanied with other signs of primary inflammation. Hypothetically, an enzymic alteration of the vitreous would give enough force to cause the retina to split apart. In any event the vitreous *is either absorbed elsewhere or is* transported into the retina. Within the retinal funnel the remnants of vitreous as seen in sections are quite different in appearance from the intraretinal protein-rich fluid. The latter usually contains a considerable number of lipid storing fatty histiocytes. These, in my opinion, are derived from the reticuloendothelial system and not from the retinal pigment layer. There is little if any disturbance in the retinal pigment layer. This layer may show a few small, late, secondary proliferations. The vascular proliferations which are often present can be identified as secondary. In general, it is possible that definite causes will be found in group 3 from the study of acute or early states. Allergic states and nutritional deficiencies underlie some massive separations in this grouping.

In the dominantly hemorrhagic form of massive separation the retina is split apart, as is usual in massive separation, at the level of the rod and cone layer. The hemorrhagic form resembles the serous type except for the addition of blood and more histiocytes and earlier fibrosis. Fibrosis and its consequences are secondary and follow the separation but do not cause it. Hyalin necrosis and partially encapsuled detritus and zones of old hemorrhage are commonly seen in sections of eyes in subacute stages. The sections of eyes in advanced stages sometimes show pronounced gliosis, at times massive in degree. Usually fibrosis, massive in degree, ties the retina down proportionally, and its elevation is only nodular and focal. The cystoid changes in late cases are of the degenerative type.

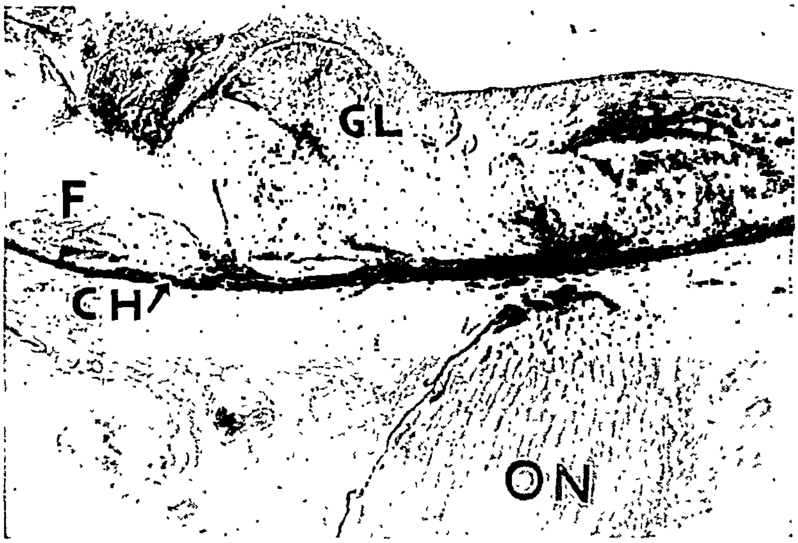

Fig. 32.—Massive gliosis of the retina, a nonspecific reaction, representing repair, usually of hemorrhage, commonly found in late stages of any inflammatory juvenile retinal separation: *GL*, gliosis within the retina; *F*, fibrosis lying over atrophic choroid, *CH*, and *ON*, optic nerve.

There are some hints in the sections that the serous type of lesion is due to an unidentified agent acting locally to provoke the vascular leakage. However, metabolic and indirect causes probably underlie most of the pathological processes of this type. Leber's retinitis exudativa serofibrinosa can be classified here.

An early state of the hemorrhagic type of massive separation of the retina is illustrated in figures 15, 16 and 17. In this case the infant was of at least eight months' gestation, with a birth weight of 4½ pounds (680 Gm.). An extreme degree of disrupting and destroying hemorrhage is illustrated in the retina. The separation is at the rod and cone level, leaving the pigment epithelium with the choroid. The retina is split by extensive hemorrhage, principally at the inner reticular layer; some secondary cystoid spaces are in this zone. The Cloquet canal area is nebulously outlined by a faint fibrillary structure within the vitreous. Eosinophilic granular cells and macrophages are scattered thinly.

The rarest example of massive separation is due to spontaneous multiple bilateral retinal cysts. This condition probably can be classified in group 3, namely, as a massive separation due to some unknown metabolic disease. The cysts appear to be a primary and not a secondary manifestation of degeneration. The cause probably is not local. The process begins, according to sections, just outside the external limiting membrane. The retina is separated at the rod and cone level from the pigment epithelium. There is but little fibrosis in the early stages. The source and force of the disruption apparently is related to the retinal or choroidal blood supply. The ophthalmoscopic findings are unusual, nearly transparent "bubbles" within the retina running anteriorly and posteriorly. It is a bilateral, painless, gradually developing process, which may bear some relationship to the cause of the bone disease as in the case used to illustrate this group. Intraocular pressure is not changed materially. Another distinguishing point is the improvement and maintenance of vision over a considerable period of time after diathermy surface coagulation. Although the underlying cause at the moment is obscure, low level anoxemia over a long ing through many sections. It is probable that it will take considerable time to establish the ocular incidence of various parasitic infections in this country. Sections of early lesions more readily show identifiable fungi and worm parasites. In either case the tissue often responds by an increase of eosinophilic cells and sometimes by a sharp increase of multinucleated plasma cells Numerous histiocytes are usually to be found along the choroidal and retinal borders of the intraretinal fluid and within the retina. Edema is excessive and some hemorrhage is present. In early cases of each infection, various cycles of the parasite are sometimes found in the choroid, vitreous and retina, especially along borders of the intraretinal fluid and in the retrolental region. A pertinent point is that edema and hemorrhage force the retina apart. It usually is not pulled off by secondary vitreous organization. In late stages fibrosis and pathological repair mask evidences of the invasion. The site of the parasite may sometimes be identified by an accumulation of inflammatory cells about a remnant. Contaminants, especially fungi, are liable to be present. It would be ideal to be able to classify pathogens from cultures. The accurate classification of species, especially fungi, depends on cultural characteristics. The pathologist ordinarily does not obtain the specimen in a fresh state, but culture and animal inoculations should be done from suspected material whenever possible. The vectors of these invaders are still to be discovered. The family pet is a likely source of nematodes. The following is an example of massive separation of the retina due to nematoid endophthalmitis:

[12] Heath, P., and Zuelzer, W. W.: Toxoplasmosis: Report of Ocular Findings in Infant Twins, Arch. Ophth. **33**: 184-191 (March) 1942.

period of time could theoretically explain the fairly uniform distribution and size of the retinal cysts. An additional discrimination from an ordinary secondary degenerative cystoid disease is its late and slow development without signs of inflammation. In the following illustrative case of bilateral primary massive cystic separation of the retina, the clear cysts appeared when the patient was about ten years of age.

A child at the age of 1 year showed a disturbance of endochondral ossification, possibly an achondroplasia, which was classified by some as eccento-osteochondrodysplasia (Morquio's disease). He became unable to walk, and at the age of 10 years there developed multiple bilateral semitransparent retinal cysts. There was no history of physical injury. The clinical characteristics were slow onset, maintenance of considerable vision for a period of years, mild vitreous opacities, low grade chronic episcleral and scleral infiltrations, and a late disinsertion of the retina. Sections of one globe showed extensive relatively uniformly severe cystoid degeneration throughout, involving inner and outer nuclear layers as well as the zone between, and the retina detached at its ora serrata insertion.

Clinical Differentiation of Massive Separations

Group	Frequency	Onset Age	Sex	Eye Size	Laterality	Inspection and Ophthalmoscopic Findings
1 Retinal aplasia and dysplasia	Rare	Congenital, either full term or premature	Either	Always small	Unilateral	Partial and extensive separation: asymmetric postlental mass, numerous vessels; retinal stalk; cataract changes
2 Specific inflammation	Rare	Birth to 15 yr.	65% males	Normal; atrophy in late stages	Unilateral; rarely bilateral	Early massive separation; inflammatory vitreous; hemorrhage variable, usually exaggerated
3 Vascular retinopathy	Rare	Birth to 10 yr.	More males	Normal	Unilateral or bilateral	Massive separation; uniformly opaque and gray; vessels partly obscured; variable hemorrhage, may be excessive
4 Neoplasm						
Retinoblastoma	Rare	1 mo. to 3 yr.	Either	Normal	Often bilateral	Flat, white retinal patches changing to pink elevated masses; vessels loop in and out
Angiomatosis	Rare	10 to 30 yr.	Either	Normal	Unilateral	Quadrant segmental orange-colored mass; varicose dilated vessels, cysts and exudates
Astrocytoma	Very rare	3 to 30 yr.	Either	Normal	Unilateral or bilateral	Patchy white elevations obscuring vessels

The cysts and small spaces were limited by Müller's fibers running perpendicular to the surface of the retina. Some of the cysts contained pink-staining granular material. Few ganglion cells were apparent, although there was less degenerative change than one would expect. Autolytic changes were mild. The inner limiting membrane was thickened. Some glial proliferations were present. The optic nerve was atrophic. These observations are illustrated by figures 18 to 21, inclusive.

Massive separation of the retina due to primary new growth is classifiable from the tissue of origin into three main types. Each shows in sections easily identifiable growth characteristics. Each has some genetic attributes. The retinoblastoma often shows an irregular dominance. The astrocytoma or true glioma is sometimes familial. The vascular growth, angiomatosis, in about a quarter of the cases is familial. The retinoblastoma often is bilateral, the angiomatosis is unilateral, and the excessively rare astrocytoma may be either unilateral or bilateral. The early clinical appearances of the malignant retinoblastoma and the benign astrocytoma are somewhat similar.

The retinoblastoma usually appears in an infant aged between 6 months and 3 years in one eye; it is liable to involve both. It is characterized by rapid growth, considerable necrosis and, sometimes, the presence of calcium. This rapidly growing tumor is exceedingly dependent on a good oxygen supply. The retinoblastoma, unfortunately, is the commonest of the three tumors. Microscopic study of this tumor shows that it may originate from either the inner or outer nuclear layers or both. The tumor often shows rosette and pseudorosette formation and mineralization.

The fibrous astrocytoma is a monocular or bilateral manifestation which is discovered in children between the age of 4 to 6 years or in young adults and is relatively stationary in growth; other siblings may be affected. Its separation of the retina is partial, gradual and, unless multicentric origins exist, not realized until about the age of puberty. It is such a rare tumor that it is unlikely ever to be seen by the average ophthalmologist.[13] The growth is so slow that often months pass before significant changes can be noted clinically. The retinal separation is first meridial and later the process becomes more massive. Sections of the astrocytoma stained for glial fibers show enormous numbers of glial cells and fibers, some with large, rounded nuclei, others more spindle-shaped. The cells are mostly of two sizes, large and small, both possessing numerous fiber processes. A few exceedingly large, ganglion-sized cells with thicker processes are present.

To illustrate astrocytoma (figs. 22-24), a female infant (whose younger sister was similarly affected bilaterally) showed at the age of 1 year a convergent squint of the left eye. Ophthalmoscopic examination at that time showed multiple greenish white patches and some elevations of the retina bilaterally. The right eye in addition had a nodule on the nerve head. Microscopic examination of the right eye revealed a thickened nerve fiber layer in the retina. Near the ora the retina was poorly differentiated. There was some proliferation of the pigment epithelium, and a hyalin pink coagulum was noted within its fibrous structure. The retina was better differentiated toward the nerve head, especially its external nuclear layer, while the inner nuclear layer remained somewhat thin. There was mild endothelial proliferation within the retinal vessels. A few lymphocytes were stranded through the choroid. The retina itself was separated by a pink-staining granular coagulum. The nerve head in association with the retina showed an elevated mass of glial tissue. Glial cells were of three types, small, large and a few extra large, many showing granules and basophilic staining. Some were decidedly spindle shaped. The large cells were three or more times the size of the smallest and often contained two nucleoli. The nerve fibrillary layer was thickened. Silver stains showed pronounced increase of glial fibers; many were swollen and varicose. Some cystic changes increased toward the ora.

---

[13] McLean, J. M.: Astrocytoma (True Glioma) of the Retina, Arch. Ophth. **18**: 255-262 (Aug.) 1937.

Angiomatosis of the retina (von Hippel's or Lindau's disease) is clinically characterized in early states by elevations of the retina in one vascular quadrant, associated with exudation and hemorrhage. Gradually there are formed decidedly dilated vessels connected by means of a large cyst or multiple cysts and increased exudations. Vasoformative tissue with nodular swellings and proliferations can often be noted with the ophthalmoscope as well as seen in sections. Microscopically, one sees angiomatous structural proliferations and greatly dilated vascular channels within the retina accompanied with extensive edema and hemorrhage in a slowly expanding tumor. The extension of the tumor causes a gradual massive separation of the retina.

of the Retina in Infants and Children

Inflammatory Changes	Intraocular Pressure	Associated Defects and Signs	Progression	Treatment
None	Normal	Common, congenital anomalies in same eye; especially a deficient secondary vitreous	Stationary	None
Congestion; vitreous opacities and retinitis vary with agent	Lowered	Uveitis and endophthalmitis; infections and parasites	Rapid retinal separation	Treat cause; prevent second eye involvement
Mild and in retina	Lowered unless secondary glaucoma from angle block	Pathological permeability; usually unknown and spontaneous causes; endocrine disease	Rapid separation of retina	None known except in the slow onset cystic form
None	Normal	None, dominant inheritance	Rapid growth (weeks)	Enucleation and/or roentgen ray
None early; low grade uveitis; secondary glaucoma from angle block may develop late	Either a late atrophy or secondary glaucoma	Cerebral and cerebellar cysts; sometimes familial	Slowly progressive (months)	Diathermy coagulation
None	Normal	Retina not fully differentiated	Very slow growth (years)	(?) Diathermy coagulation

An example of angiomatosis (figs. 25-31) occurred in a girl 13 years of age, whose mother, now living and well, at the age of 13 years had a similar blind right eye which was enucleated ten years after its discovery. The child's eye had been blind one year. Ophthalmoscopic examination showed in the right eye a large, yellowish white retrolental mass. Many small vessels, some with irregular dilatations in the walls, were seen. There was complete separation of the retina. Examination of the normal-sized enucleated eye showed an anterior vascular membrane of the iris and some anterior adhesions partially blocking the angle. The retina was separated by extensive serum, hemorrhage and dilated neovascular structures; it contained a considerable number of fat-laden histiocytes. The decidedly edematous retina showed an increased thickness of the nerve fibrillary layer, many large and newly formed vessels, and cystic spaces. Nodules of gliosis and fibrosis had formed on the choroid. The vitreous contained excessive fibrin and also was partly organized. Cholesterin clefts were conspicuous in the retina and in the heavily eosin-stained intraretinal fluid. The pigment layer of the retina showed some proliferation and remained with the shrunken choroid.

DIFFERENTIAL DIAGNOSIS

Clinical diagnosis is more difficult to make than diagnosis from sections of pathological tissue. Ophthalmoscopic examinations alone are often inadequate for diagnosis. It is necessary to utilize all available information to arrive at a tentative diagnosis. When the retina is hopelessly compromised and the diagnosis is doubtful, the eye should be removed. This permits a microscopic examination which may save the patient's life or may show means of preventing the involvement of the second eye. A summary of clinical differentiations is presented in the accompanying table.

COMMENT

A study of the classification of massive separation of the retina in full term infants and juveniles will show that congenital developmental anomalies are placed in group 1, that group 2 contains the large field of inflammation from many specific causes, that separations due to little understood or unknown causes repose in group 3 and that group 4 pertains to neoplasms. The common and unifying manifestations in this classification are the point of attack and the consequences, namely, a retinal disease and a massive separation. Acute stages of these retinal diseases are quite different in appearance and easier to classify. Late stages of the retinopathies tend to resemble one another when secondary reparative reaction tends to mask or conceal the primary disease. Late stages of several kinds of retinopathy will show similar fibrosis and gliosis, sometimes massive in degree, as part of the repair from hemorrhage (figs. 32 and 33). Pigment is transported variously and decorates the scar tissue irregularly. But these observations represent changes in degree of pathological repair and should not be confused with specific diseases. A considerable list of merely descriptive terms can be jettisoned by the adoption of the classification based on cause. Additional advances will be reached by further elucidation of causes in the group 3 patients — those with unexplained vascular permeability. Some patients in this group at present classified as possessing an unknown metabolic disease will have some basic causative factor established to explain the vascular permeability; others probably will remain in this group as possessing a metabolic disease identifiable as an endocrine dysfunction. A considerable advance is made, I believe, in establishing a definite framework for classification. In group 2, which is representative of specific inflammations, some agents (like tuberculosis and meningococcic meningitis) and other metastatic and local septic processes and some parasites have long been recognized. Two newcomers emphasized here are retinal diseases and massive separations due to mycotic and parasitic infections. Endophthalmitis due to a fungus can occur in infants, juveniles and adults, and it can also be a congenital disease maternal in origin. The parasitic worms are more liable to be acquired during juvenile life. But parasites can be acquired by the premature after birth and may cause massive separation.

A third and apparently new and rare type of massive bilateral separation which originates from multiple retinal cysts is described herein. A fourth exceedingly rare cause is the benign growth, astrocytoma, which can occur in young juveniles and siblings. It is probable that these relatively slow growths may be discovered in adult life, although the first manifestation was not recognized in juvenile life. The frequency of the various causes of massive primary retinal separations will only be established after extended study.

CONCLUSIONS

Massive separation of the retina in infants and juveniles is caused by many factors and agents. The incidence of each etiological factor remains to be determined. A sufficient number of these are recognizable to justify a classification based on causative factors and/or the principal primary pathological manifestations.

A significant cause of massive retinal separation in juveniles is endophthalmitis due to parasitic infection.

The terms pseudoglioma and Coats's disease are misleading, and nondescriptive, and should be dropped. Some examples of massive separation of the retina due to rare causes are reported, namely, fungus infection, Cryptococcus neoformans, primary cystic retinal disease and astrocytoma.

243 Charles Street (14).

ABSTRACT OF DISCUSSION

Dr. Michael J. Hogan, San Francisco: This paper is instructive because it helps clarify the confusion created by recent extensive discussions on retrolental fibroplasia. I was struck by the number of authors who considered diseases of this type as purely of inflammatory origin. It is surprising that, in view of Coats's original observations, more effort has not been expended to expose the vascular nature of some of these lesions, which at present is only partially known. I agree with Dr. Heath that the terms pseudoglioma of the retina, Coats's disease, external exudative, hemorrhagic or massive retinitis and massive gliosis are inexact and unsatisfactory. One has at least a chance in the early stages to establish the causative factor in these cases, but in the later stages it is difficult or impossible. If the patient exhibits signs of a coincident systemic disease the diagnosis may become even more evident. In the later stages when reparative processes are complete it is impossible in most instances to make either a clinical or pathological diagnosis. I would like to ask Dr. Heath whether it would not be better to classify cases of this type as (1) congenital, due to (*a*) developmental defects, (*b*) acquired inflammation during gestation or (*c*) trauma, and (2) infantile and juvenile, due to the etiological factors proposed in his paper. I noted that he omitted trauma as a possible etiological agent, and wonder whether he would include these cases in group 3 or devise a new heading. I find it difficult to accept the heading in group 3, namely, pathological vascular permeability with separation of the retina by excessive edema or hemorrhage. Would it not be better to classify these cases as either vascular or circulatory and then attempt to subclassify the causative factor? As an example, may not angiomatous malformations, leakage from or rupture of fusiform or saccular aneurysms, and sudden arteriovenous communications produce these lesions? It is also possible that an infective embolus may erode a vessel and cause a profuse hemorrhage, thus completely masking the original cause. A serious objection to this concept is that most of these lesions should occur in the vessels of the inner retina. The resulting hemorrhage should be in the inner retina and adjacent areas; nevertheless, I know of several cases of this type which demonstrate angiomatous changes. In Dr. Heath's case of hemorrhagic type of massive separation in an infant born at eight months, the cause of death at 27 days of age was not stated, and it would be interesting to know whether there was any birth trauma, cerebral hemorrhage or evidence of prolonged asphyxia.

Dr. Parker Heath, Boston: When one attempts a classification in a field of this sort, the initial effort usually is extremely complicated, and with time one revises it more and more until ultimately it is reasonably simple. I would not quarrel with Dr. Hogan about the choice in terminology of "circulatory" or "vascular"; either would be acceptable. I think that the net result of the various types of vascular injury presented is a pathological permeability, serous or hemorrhagic. Consequently, the term "vascular" was used with the subtitle, "pathologic permeability." This seems to me more inclusive than any other terminology that could be used. In the matter of the congenital monocular defects, these are encompassed by the terms retinal aplasia or dysplasia. It is with some temerity one follows such men as Coats and Collins and attempts to alter their descriptive nomenclature, but I believe that causation is manifested in a high enough percentage of this group of patients to permit a definitive classification. It has proved to be practical in the hands of the clinicians and offers a basis for treatment and prevention.

LATERAL PHARYNGEAL DIVERTICULA AS A CAUSE OF DYSPHAGIA

JACOB BUCKSTEIN, M.D.
and
STANLEY REICH, M.D.
New York

A comparatively rare cause of dysphagia not ordinarily considered in differential diagnosis is that of lateral pharyngeal diverticula. Recently we have had two examples of this disorder. In this condition the diverticula project anterolaterally from the hypopharynx at about the level of the pyriform sinuses.

We include herein a brief survey of the embryology of this condition. The lateral surfaces of the neck of the embryo become indented by four bilaterally-paired branchial grooves during the fourth to fifth weeks of embryonic life. Concurrently, four bilateral pairs of branchial or pharyngeal pouches arise internally from the lateral walls of the pharynx. These grooves and pouches correspond and lie opposite each other. Each pair is separated from the next by the branchial arches. An unpaired median outgrowth also appears in the floor of the pharynx.

The single ventral outgrowth is the thyroid diverticulum, which becomes the thyroid gland. The first pharyngeal pouch becomes the eustachian tube, middle ear and mastoid antrum. The second becomes the Rosenmüller groove in the supratonsillar fossa as well as the epithelial lining of the palatine tonsil. The third gives rise to the parathyroid glands, thymic corpuscles and reticulum of the thymus gland. The fourth leaves no definite remnants in man. The third and fourth pouches merge to form the pyriform sinus, with the dividing line at the level of the plicae nervi laryngei.

The third pouch is anterior and the fourth pouch posterior to this structure. In our patients the diverticula apparently arose from either the third or fourth pouches which were not obliterated during the normal course of development. The roentgen anatomy of the normal hypopharynx has been described elsewhere.[1]

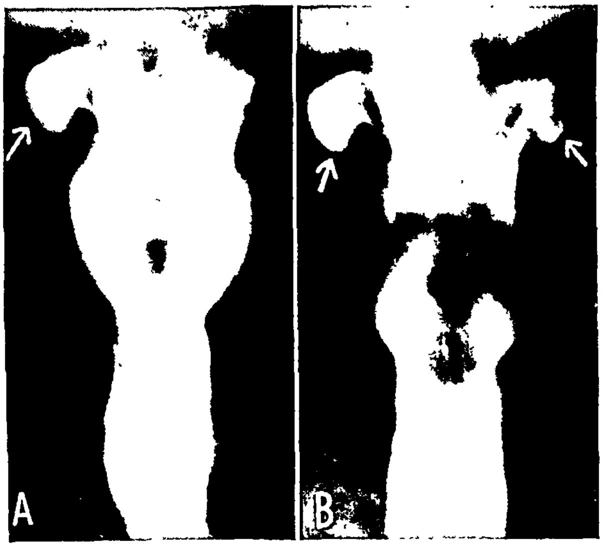

Fig. 1 (case 1).—*A*, spot film of the hypopharynx completely distended with barium, showing only the right lateral pharyngeal diverticulum. *B*, spot film of the hypopharynx showing the right and left lateral pharyngeal diverticula. This method was the only means of demonstrating this condition since the hypopharynx emptied itself of barium so rapidly. However, this does not imply that food particles would not be lodged in these diverticula and thereby cause the symptoms of which the patient complained.

Symptomatology.—The complaint is that of dysphagia. Since the diverticula retain food, the patient has a sense of fulness in the neck. One may relieve this by either emptying the sac by change in position or lavaging the diverticulum while drinking water. For obvious reasons, food which is regurgitated after being eaten will be found to be completely undigested.

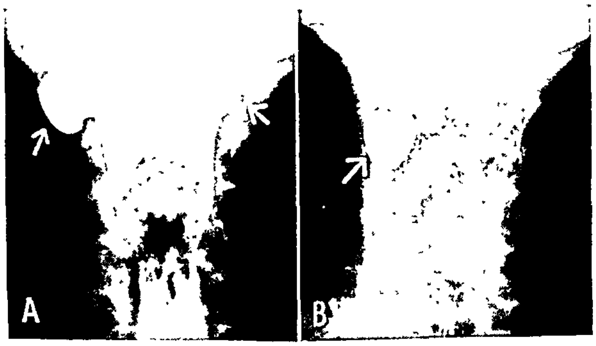

Fig. 2 (case 2).—*A*, the large pharyngeal diverticulum extending laterally on the right side. A smaller diverticulum may also be noted on the left side. This is not completely filled with barium. *B*, with the hypopharynx only partially distended with barium, the centrally placed bilateral valleculae may be noted. On the right side is the oval pharyngeal diverticulum. The diverticulum on the left side is not seen because it is not distended with barium. Barium was present in the right lateral diverticulum for several hours. This would explain why pills stuck in the patient's throat and why he regurgitated undigested food.

REPORT OF CASES

The clinical manifestations and the roentgen appearance of this disorder are illustrated by the following two cases:

Case 1.—H. L., a man aged 54, for three years prior to examination complained of food sticking in his throat. He stated that he had to swallow "real hard" to get it down. He had more difficulty in attempting to swallow solid food, but occasionally he also had difficulty with liquids. At times he might be free of dysphagia for as long as one month. He had been gaining weight, and there was no vomiting. Fourteen years previously he had been operated on for a perforated peptic ulcer, and except for a mild recurrence seven years later he remained free of gastric symptoms.

Case 2.—H. D., a man aged 45, stated that during a period of 20 years pills "stuck in his throat." During the same length of time he frequently regurgitated undigested food, sometimes three days after ingestion. In addition, the patient gave a history of peptic ulcer of 20 years' duration and an operation 11 years previously for a perforated duodenal ulcer. He had lost 26 pounds (11.8 Kg.) in the preceding three years.

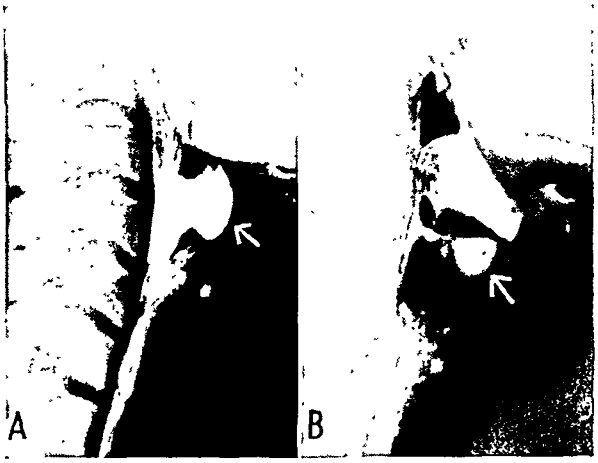

Fig. 3. (case 2).—*A*, right lateral position of the pharynx. Note the appearance of the large right pharyngeal diverticulum extending anteriorly. The valleculae were not filled with barium at the moment when the exposure was made. *B*, right lateral view of the hypopharynx. At this time the barium-filled right vallecula is clearly seen partially overlapping the right pharyngeal diverticulum below.

SUMMARY

Two cases of lateral pharyngeal diverticula as a rare cause of dysphagia are reported. With this condition in mind it is possible that physicians will discover more cases of this nature, particularly if spot film studies are made of the barium-filled hypopharynx.

Air Embolism.—An air embolus differs from a solid embolus in several ways. Whilst solid material will pass with the blood stream and stick in a vessel of its own diameter, the distribution of air is partly determined by the simple fact that bubbles in fluid will rise, and so air tends to reach the highest vessels. It has been shown experimentally that air bubbles do not pass into vessels of less than 40μ in diameter. Bubbles of this size in blood behave more like plastic solids than viscous liquids. The effects of air embolism are produced not only by mechanical blockage of blood flow, but also, since air is irritant to the vessel, by peripheral vascular spasm distal to the embolus, such as occurs with solid emboli. Apart from air embolism there are few causes of the appearance of gas in blood vessels. Decomposition and gas gangrene are unlikely to confuse the pathologist and in the case of the "bends" (caisson disease) the history will be clear. Occasionally, however, air gets into cerebral cortical vessels when the skull cap is taken off at autopsy, and it may enter the neck and other veins when these are severed. Therefore in performing an autopsy in a case of possible air embolism, the brain should be examined before the neck veins are opened or other organs removed.—C. Allan Birch, M.D., F.R.C.P Air Embolism, *The Practitioner*, August 1950.

AUREOMYCIN IN THE TREATMENT OF INFLUENZA

A Controlled Study

MAJOR WILLIAM G. THALMANN
Medical Corps, United States Army
C. HENRY KEMPE, M.D.
San Francisco
CAPTAIN JOSEPH A. WORRALL
Medical Corps, United States Army
and
GORDON MEIKLEJOHN, M.D.
Berkeley, Calif.

This report deals with a controlled study of the use of aureomycin in the treatment of influenza, type A′, in a military installation during the winter of 1949-1950. The study includes a total of 150 cases of serologically proved influenza A′. Of the 150 patients, 69 were treated with aureomycin, 43 were treated with penicillin and 38 received no chemotherapeutic agent.

PATIENT MATERIAL

The patients included in this study were a group of previously healthy young men, who were engaged in basic military training at an Army Post and who were admitted to the medical wards of an Army Station Hospital. The epidemic of influenza began abruptly during the first week of January 1950, rapidly reached a peak during the third week of January and subsided almost as abruptly during the following three weeks.

CLINICAL DESCRIPTION OF AVERAGE CASE

In general, the patients presented themselves with histories of an illness which was sudden in onset and which was characterized by chilliness and fever, malaise, retro-orbital pain, generalized aches and pains and soreness of the throat. In the majority of cases some degree of cough was present. In most instances these patients appeared acutely ill on admission. All were febrile. Temperatures ranged from 99 to 104 F. on admission to the wards, and in approximately one third of the patients the maximum temperatures were 103 F. or higher. Physical examination usually revealed little except the frequent occurrence of conjunctival injection, diffuse redness of the nasal and pharyngeal mucosa and occasionally the appearance of dry or moist rales in the lungs. Except in a few cases, the disease was of moderate severity and was similar clinically to that in other outbreaks encountered by us during the past four epidemic years. Complications included five cases of roentgenographically proved pneumonia resembling in appearance primary atypical pneumonia. Bacteria regarded as etiologically significant were not isolated from any of these five patients. No complications proved to be of bacterial origin were encountered.

METHODS OF STUDY

Immediately on their arrival in the hospital, the patients were admitted to wards specifically instituted for the handling of acute respiratory illnesses. During the first half of the epidemic these patients were assigned alternately either to the aureomycin-treated group or to the penicillin-treated group, depending entirely on the time of their arrival in the ward. During the latter half of the study, patients were similarly assigned to treatment groups, a change being made, however, in that during this period every other patient was treated with aureomycin and every other patient received no chemotherapy. This grouping of patients as to treatment applied to all admissions to these wards during the period of the study; since not all these patients were found to have influenza and since only cases of proved influenza are considered here, the number of patients treated with aureomycin is not identical with the total number of patients who received penicillin or no chemotherapeutic agent.

All laboratory studies were initiated prior to institution of therapy. In addition to routine blood counts and urine examinations, throat and sputum cultures were done on each patient. Blood cultures were taken on patients who appeared most severely ill or who had evidence of pulmonary involvement. Serologic studies were done on all patients admitted to the wards. These included tests for complement-fixing antibodies on paired acute and convalescent serums for influenza A and B and for agglutination-inhibiting antibodies in those instances in which the results of former tests were inconclusive. Cold agglutination tests were done on all convalescent serums. Throat washings from six representative patients were inoculated into ferrets or fertile eggs for isolation of virus. Chest roentgenograms were taken when physical findings indicated.

Table 1.—*Analysis of Dosage*

Drug	Mean Total Dose	Mean Duration of Treatment, Days
Aureomycin	4.2 Gm.	4.2
Penicillin	2,700,000 units	4.5

Table 2.—*Analysis of Results*

Group	No. of Patients	Duration of Illness		Mean Interval Before Sustained Temperature Drop,* Hours
		Mean Total, Days	Mean in Hospital, Days	
Aureomycin treated	69	4.7	2.7	39.0
Penicillin treated	43	4.2	2.7	39.5
Untreated	38	4.9	3.0	40.6

* This is the mean interval between admission to the hospital or initiation of treatment and sustained temperature drop to 99 F. or lower.

CRITERIA FOR DIAGNOSIS OF INFLUENZA

All 150 patients with diagnoses of influenza A′ showed a rise in titer of fourfold or more in either the complement fixation or the agglutination inhibition tests, or in both. Virus strains isolated from throat washings of five patients during the epidemic were of the A′ type.

DOSAGE OF AUREOMYCIN AND PENICILLIN

Aureomycin was given orally in doses of 0.25 Gm. every six hours for a total daily dose of 1.0 Gm. This amount of aureomycin, one-half to one-fourth the dose frequently used, was selected because serum levels in patients receiving this dose have been found to be not much lower than those in patients on larger dose schedules[1] and because gastrointestinal toxicity has been of negligible importance in patients on the smaller dose schedule. In addition, in our experience in treating primary atypical pneumonia,[2] the therapeutic effects

---

The aureomycin was supplied by the Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y.

These studies were carried out under the auspices of the Commission on Influenza, Armed Forces Epidemiological Board.

[2] Shragg, R. I.; Castagno, A. J., and Meiklejohn, G.: Aureomycin in the Treatment of Primary Atypical Pneumonia, unpublished data.

observed with smaller amounts of the drug have compared favorably with those with larger amounts. Penicillin, in the form of an aqueous procaine preparation, was given intramuscularly once daily in doses of 600,000 units. An analysis of dosage is given in table 1. Symptomatic treatment, including the use of antipyretic drugs, was held to a minimum.

ANALYSIS OF DATA

Data were analyzed with respect to total duration of illness, duration of illness observed in the hospital and duration of fever after therapy was initiated. The total duration of illness was determined as the time interval between the onset of symptoms and complete clinical recovery of the patient. The duration of fever after therapy was measured as the time interval between the onset of therapy and a sustained fall in temperature to 99 F. or below. In the untreated group, the corresponding interval of sustained drop in temperature to 99 F. or below was measured from the time of admission. Since in the majority of cases there was a variable time lag between admission of the patient to the hospital and the initiation of treatment in the groups treated with penicillin or aureomycin, proper correction for this lag was made in determining this interval in the group receiving no treatment.

ANALYSIS OF RESULTS

Results are tabulated in table 2. The mean duration of illness was 4.7 days in the aureomycin-treated group, 4.2 days in the penicillin-treated group and 4.9 days in the untreated group. The mean duration of illness in the hospital was 2.7 days in the aureomycin-treated group, 2.7 days in the penicillin-treated group and 3.0 days in the untreated group. The mean interval between institution of therapy and a sustained fall in temperature to 99 F. or below was 39 hours in the aureomycin-treated group and 39.5 hours in the penicillin-treated group. In the group receiving no treatment, the corrected mean interval between admission to the hospital and a corresponding fall in temperature was 40.6 hours.

COMMENT

In a previous study of the effect of aureomycin on influenza,[3] it was reported that the use of this drug in 18 cases was followed by rapid improvement and relief of symptoms. The authors pointed out that no parallel cases were observed without therapy. The patients were selected for aureomycin therapy because of the severity of their symptoms and actual or suspected pulmonary complications. Bacterial pathogens were found in the throat cultures of a number of patients without pneumonia but were not found in sputums of any patients with pneumonia.

In the present study the situation differed in several respects. The patients were all previously healthy young adults who were found during their hospitalization to have an extremely low carrier rate for bacterial pathogens. In addition, the patients were wholly unselected and represent a cross section of all patients with influenza during this epidemic. In this situation there was no evidence that aureomycin or penicillin influenced the course of the disease. In a different situation, with a different virus or with a high carrier rate for respiratory bacterial pathogens, a reduction in complications might result from the use of aureomycin or other antibiotics.

The question can be raised whether a larger amount of aureomycin, such as the 4.0 Gm. dose used in a previous study, might have produced a more favorable result than the 1.0 Gm. daily dose used in the present study. In answer to this it should be noted that the mean duration of fever in the untreated patients was only 40.6 hours after they had reached the stage of their illness when treatment would have been begun. This is within the mean period generally allowed for an effective chemotherapeutic agent to cause a return of temperature to normal. If this assumption is valid, the dose and, for that matter, the use of the drug lose much of their relevance.

CONCLUSIONS

In a controlled study of the effect of aureomycin in the treatment of influenza A′, in 150 consecutive unselected cases occurring during an epidemic, the course of the illness in patients treated with this drug was not significantly different than that observed in patients who received penicillin or no chemotherapy at all.

CLINICAL PHYSIOLOGY OF POTASSIUM

WILLIAM S. HOFFMAN, M.D.
Chicago

Though it has been known that the cell membranes are freely permeable to water, dextrose, oxygen, carbon dioxide, urea and other nutrient and excretory products, it was believed in the past that they were impermeable to sodium, potassium and other electrolytes. That is how the great difference in concentration of these ions on the two sides of the membrane was explained. Ideas on this subject have been sharply modified in the last few years, and this modification has led to a much better understanding of the clinical physiology of potassium and to better therapy of dehydration. Studies with radioactive isotopes of sodium and potassium and with heavy water [1] have shown that the cells are permeable to sodium and potassium. This permeability is slow compared with that of water. When heavy water was injected intravenously by Moore,[1a] equilibrium with the total body water was established in 120 minutes. When radioactive sodium was injected, equilibrium with extracellular sodium was reached in 60 minutes but not with total body sodium until 24 hours. Radioactive potassium requires 15 hours before reaching equilibrium with cellular potassium.

The average concentration of serum potassium in normal human subjects is about 4.7 milliequivalents per liter (18.2 mg. per 100 cc.). The range of normal is from 4.0 to 5.4 milliequivalents per liter (16 to 21 mg.) per 100 cc.[2] In the intracellular fluids, the concentration of potassium is much higher, for here potassium is the principal cation, the cellular sodium concentration being low. If the recent data [1b] on dogs can be translated to human subjects, the average normal potassium concentration in all cellular fluid is about 115 milliequivalents per liter of cellular water, or some 23 times

that of the serum. The total potassium content of the adult body is about 4,000 milliequivalents (160 Gm.), of which only 70 milliequivalents (2.7 Gm.) is in the extracellular fluids (fig. 1).

There is no adequate explanation of how and why the tissue cells acquire and maintain so much higher a concentration of potassium than that of the serum or interstitial fluids. Since it has been repeatedly demonstrated that potassium leaves the cells during potassium losses from the body [3] and enters cells during its administration,[4] it appears then that there is normally an equilibrium being maintained between the low extracellular concentration and the high cellular concentration. This equilibrium is unstable, to be sure, in opposition to osmotic forces which tend to equalize the concentrations. It is reasonable to believe that this unstable equilibrium is being maintained by the oxidative energy of the cells. If this be so, then cellular anoxia would tend to send potassium out of the cells into the extracellular fluids. Such a phenomenon might account for the rise in serum potassium concentration with exercise [5] and in agonal states and might explain the progressive transfer of red cell potassium to plasma in stored blood.

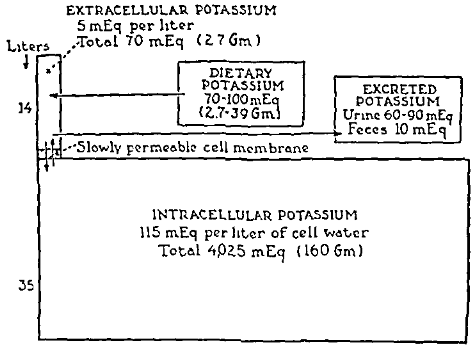

Fig. 1.—Normal distribution of body potassium.

Factors tending to increase serum potassium concentration are (1) increased potassium intake, (2) oliguria or anuria, (3) tissue breakdown or anoxia, (4) contraction of extracellular volume by dehydration and (5) adrenal cortical deficiency. Factors tending to decrease serum potassium concentration are (1) limitation of food intake, (2) increased renal excretion of potassium —(*a*) diuresis, (*b*) acidosis and (*c*) adrenal cortical hyperactivity—(3) dilution of extracellular fluid with potassium-free fluids, (4) vomiting or diarrhea and (5) glucose uptake by cells. Actual serum potassium concentration is determined by balance of all factors operating at the moment.

The equilibrium between extracellular and intracellular potassium is constantly being interfered with by a number of events which serve temporarily to raise or lower unduly the concentration of serum potassium, because they occur faster than the slow permeability of the cell membrane permits the reestablishment of equilibrium. The most important of these factors are as follows:

1. Potassium is constantly being excreted from the body by a renal mechanism designed for efficiency in removing excess potassium rather than conserving it during deficiency. The renal losses are exaggerated by diuresis, acidosis and excess adrenocortical hormone.

2. Potassium is present in the gastrointestinal secretion in high concentration. Gastric juice may at times contain as much as 40 milliequivalents of potassium per liter.[6] The concentration in intestinal juices is usually 8 to 10 milliequivalents per liter.[6a] Normally almost all the potassium in these secretions is absorbed through the mucosa back into the blood, so that the daily feces seldom contain more than 10 milliequivalents. But in diarrhea or vomiting, the losses of potassium may be 10 to 20 times that amount.

3. From 70 to 100 milliequivalents of potassium are usually ingested daily with food. After a meal rich in potassium, the serum potassium level rises slightly but soon subsides to the previous level. In the normal adult person none of this potassium intake is stored; instead it is excreted in the urine.[7] In gastrointestinal disease not only is potassium of the secretions lost with vomiting or diarrhea but the normal ingestion of potassium is prevented, while the kidneys continue to excrete potassium.

4. In starvation, trauma and disease, cellular breakdown occurs. The potassium of these destroyed cells is added to the extracelluar fluid often at a rate greater than that at which it can be removed either by excretion or by transfer to cells.[8] For every gram of nitrogen broken down, about 2.4 Gm. of potassium are released.

5. Glycogenesis carries potassium from extracellular fluid into the cells. This process occurs in specialized tissue that contains glycogen, such as liver and muscle. It is increased by glucose ingestion, by insulin and by epinephrine.[9] The fall in serum potassium levels is rapid (a matter of minutes) but temporary. In the normal persons the change in serum potassium concentration is negligible, but in potassium-deficient persons, like those with diabetic acidosis, the rapid decline of an already low serum potassium concentration may produce serious symptoms. The phenomenon occurs in extreme degree in familial periodic paralysis.

6. Expansion of the extracellular fluid compartment in the treatment of dehydration by intravenous administration of potassium-free fluids produces a rapid lowering of the serum potassium concentration, because of (1) dilution of the extracellular compartment by the injected fluid, (2) influx of water from cells to lower the osmotic pressure of the interstitial fluid and raise that of the cellular fluid and (3) increased excretion of potassium.[10] When the cells have already lost much water some of the transfer of water from the cells is ultimately annulled by transfer of sodium into the cells.

7. When potassium is lost from the body via the kidneys or the gastrointestinal tract, a good portion of it is accompanied by chloride, which has come from the extracellular fluids. This unbalanced loss of extracellular anions is compensated for by a rise in extracellular bicarbonate. That is apparently why acute potassium

deficiency is usually associated with alkalosis.[11] If such alkalosis is treated by administration of sodium chloride solutions, more potassium is lost, if renal function is good, along with chlorides; the alkalosis tends to persist, and edema is produced. On the other hand, administration of potassium chloride raises intracellular potassium concentration and that of extracellular chloride and dissipates the alkalosis.

8. Except possibly in the case of familial periodic paralysis—and maybe even there—a low serum potassium concentration always means potassium deficiency, though the intensity of that deficiency cannot usually be diagnosed from the serum level itself.[12] On the other hand, potassium deficiency may be present when serum potassium concentration is within normal limits or even higher than normal. For example, a 15 per cent loss of potassium from the body (equal to 24 Gm.) may produce a drop of serum potassium from a level of 5.2 milliequivalents per liter to 4.4 milliequivalents per liter, if equilibrium has been established. The latter concentration is still within normal limits. What probably is more important is the fact that conditions associated with severe losses of potassium also produce a breakdown of body tissue; the potassium released from these destroyed cells into the extracellular fluid, in association with dehydration and with limited renal output, may raise the serum potassium concentration momentarily to normal or even higher than normal values. The true state of affairs can usually be recognized by serum potassium analysis after several liters of saline solutions have been administered.

CLINICAL MANIFESTATION OF HYPERPOTASSEMIA AND HYPOPOTASSEMIA

Symptoms of hyperpotassemia chiefly involve the heart. Paresthesias of the extremities and flaccid paralysis have been reported,[13] but in most instances the cardiac observations are the only significant ones. There are characteristic electrocardiographic changes.[14] The T wave becomes increasingly taller with a narrow base; this can be seen with serum potassium levels of 7.5 milliequivalent per liter (29.3 mg. per 100 cc.). With higher levels, as the T wave becomes even higher, the QRS complex becomes progressively broader, indicating intraventricular conduction defect. The P wave may disappear. Ultimately the heart stops in diastole. Death can occur when the serum level reaches 10 milliequivalents per liter (39 mg. per 100 cc.), but reversible changes have been known to occur even at higher levels.[15] It is important to recognize that these changes are due entirely to the extracellular accumulation of potassium. The intoxication may take place even in the presence of severe cellular deficiency of potassium. That is why it is important to administer potassium slowly and preferably via the stomach, even in pronounced deficiency; extreme care is required when renal function is too poor to permit rapid adjustment of the serum potassium concentration.

Since in almost all instances of hypopotassemia there is pronounced cellular deficiency of potassium, many of the symptoms may be due to the latter rather than to the low serum levels.[12] Yet the fact that the muscular paralysis of familial periodic paralysis occurs when the serum potassium level falls as a result of potassium entering the cells makes it certain that the low serum level is responsible for this symptom. In familial periodic paralysis it is usually the muscles of the extremities that are seriously involved; in diabetic acidosis following insulin treatment, it is the respiratory muscles that are affected. Perhaps it is the most fatigued muscles that show the greatest effect of the low serum potassium.

The electrocardiographic observations associated with low serum potassium concentrations are in several respects the opposite of those found with high serum potassium levels and are therefore probably directly due to the low extracellular potassium concentration.[16] There is progressive lowering and broadening of the T wave and lengthening of the Q-T interval. The S-T segment usually becomes depressed. As the serum potassium falls still further a U wave may make its appearance. All these abnormalities may disappear on the raising of the serum potassium concentration by injection of potassium salts.

There are other clinical manifestations associated with low serum potassium levels which are probably produced by the cellular deficiency in potassium. Unfortunately these symptoms are not specific; they may be found in many debilitating conditions. They are extreme muscular weakness, anorexia, lethargy, distention of the intestine, myocardial degenerative changes and edema of the lungs. Often these symptoms become evident after much saline therapy.[17]

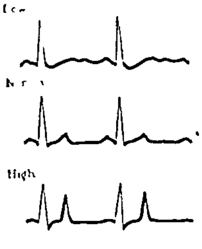

Fig 2—Electrocardiograph changes (idealized) produced by changes in serum potassium concentration, shown for unchanged heart rate

CLINICAL CONDITIONS INVOLVING VARIATIONS IN BODY POTASSIUM

Diabetic Acidosis. — During the development of acidosis,[18] glucose and keto acids are excreted in large quantities, carrying with them much fixed base. There is an accompanying polyuria. In addition, vomiting in these cases enhances the loss of water, fixed base and chloride. The resulting contraction of extracellular fluid volume and lowering of its sodium, chloride and bicarbonate content is well known. But it is now recognized that large losses of potassium also occur, even though the serum concentration at the height of dehydration may not be lowered.[19] The dehydration not only is extracellular accompanied by sodium and chloride loss but is intracellular with potassium and phosphate loss. Treatment in the past has been to give insulin, isotonic sodium chloride solution and alkali, either as sodium bicarbonate or as sodium lactate. In most instances, when the patient has not been dehydrated and acidotic to the point of collapse, this

treatment is satisfactory, for the patient is quickly brought back to consciousness. Then oral administration of milk and orange juice furnishes the necessary glucose, calories and potassium to permit rapid convalescence. In some instances, however, consciousness does not return so fast. In these, further injections of saline and lactate solutions, along with insulin (with or without dextrose) produces a characteristic train of events. First the extracellular fluid is expanded and the serum potassium level falls. The improved renal function produces a further loss of potassium. Then the sudden availability of insulin with its accompanying glycogenesis in liver and muscle produces a rapid transfer of extracellular potassium into these tissues. The consequence of all of these factors is an abrupt fall of serum potassium to a level producing respiratory paralysis and cardiac damage. That is why a number of patients in deep diabetic coma treated this way have appeared to improve at first and have then become worse and died. This catastrophe can be avoided in many instances by the judicious use of potassium chloride along with sodium chloride and sodium lactate. The potassium chloride should be given preferably by mouth or stomach tube, 2 Gm. at a time. It may be given successfully by proctoclysis. If given intravenously, a liter of fluid should not contain more than 2 Gm. of potassium chloride.

Infantile Diarrhea.—Darrow and his co-workers [20] have made balance studies in infants recovering from severe infectious diarrhea. Those infants who were given potassium in addition to sodium, chloride, dextrose and lactate made the most rapid recoveries and had a negligibly low mortality rate. Darrow demonstrated that during the period of diarrhea the losses per kilogram of body weight were water, 125 Gm.; chloride, 9.2 milliequivalents; sodium, 9.5 milliequivalents, and potassium, 10.4 milliequivalents (table 1). The water loss was equal to one half of the total extracellular fluid. However, if one assumes that the lost chloride was all extracellular, then about one third of the lost water came from the cells. The sodium loss from extracellular fluid should have been about 25 per cent more than that of chloride; therefore, that portion of the sodium had not left the body at all but was in the cells replacing part of the 10 milliequivalents of potassium lost from the cells. The loss of potassium represents about 15 per cent of the total body store of potassium. When these infants were treated with fluids not containing potassium, they continued to lose 1 to 1.5 milliequivalents of potassium per kilogram per day; but, if the repair solutions contained adequate quantities of potassium, positive balances of potassium up to eight milliequivalents per kilogram could be obtained in three days. However, Darrow learned that if potassium was given in the presence of circulatory and renal inefficiency, the serum potassium concentration rose rapidly to dangerous levels. Therefore, he recommended initial intravenous infusions of isotonic sodium chloride solution and 5 per cent dextrose along with blood or plasma until circulatory and renal function had been restored. Then he gave subcutaneously a solution containing 0.4 Gm. of sodium chloride, 0.26 of potassium chloride and 0.59 of sodium lactate. This fluid (now called Darrow's solution) can also be given orally, diluted with two parts of five per cent dextrose in water, whenever the clinical condition permits this avenue of administration.

Butler and his associates [21] have come to essentially the same conclusion. Their repair solution is more hypotonic and contains relatively less sodium and more potassium. They, too, recommend initial treatment with saline solution and blood if circulatory and renal failure is present.

Surgical Conditions.—Randall and his co-workers [61] have shown with balance studies preoperatively and postoperatively on surgical patients that the potassium losses were two to three times higher than would be anticipated from the nitrogen loss. Therefore, this extra potassium came from intact cells. The loss occurred not only because of potassium deprivation in the presence of normal urinary excretion but because of removal of potassium by vomiting, suction drainage and diarrhea. In addition to these losses, additional potassium was excreted in the urine as part of the alarm reaction that occurred with the disease and the operative management. These authors found that patients who received, in addition to the usual alimentation with saline solutions, dextrose and amino acid solutions, 2 Gm. of potassium daily preoperatively and postoperatively, did not have negative balances of potassium and for the most part maintained normal serum potassium levels.

Uremia.—As early as 1934 I [2] reported that the serum potassium levels in uremia may be low, normal or high. This observation has been confirmed many times.[22] Modern studies of renal excretion of potassium clarify [23] the causes of this variability of potassium concentration. A normal intake of 70 milliequivalents of potassium requires a potassium clearance of only 10 cc per minute to maintain the normal potassium concentration. Since about 130 cc. of plasma are cleared of potassium by glomerular filtration, the normal kidney must reabsorb more than 90 per cent of the filtered potassium to keep from exhausting the body supply. Actually, even more potassium than is filtered is present in the fluid reaching the reabsorbing tubular cells, for some potassium is also excreted by tubular excretion. *The quantity reabsorbed varies inversely with the serum* potassium concentration, so that excretion is more effective when excess potassium is in the extracellular fluids.

There is probably a hormonal inhibition of this reabsorption. Other factors, such as osmotic diuresis and the excretion of large quantities of acids, also limit the reabsorption of potassium. In nephritis with a diminution of glomerular filtration, potassium filtration becomes diminished, but tubular excretion may not be interfered with to such an extent. Furthermore, tubular reabsorption more distally is less complete because of the rapid flow and because of damage to the tubules. As a consequence the clearance of potassium may remain higher than 10 cc. per minute, even when the glomerular filtration rate is less than that, so long as there is no oliguria (table 3). Since uremic patients usually eat poorly and have frequent spells of vomiting or diarrhea, the total effect may actually be potassium deficiency with low serum potassium concentration. However, if the intake is large, the serum potassium levels may be normal. If oliguria sets in and is associated with tissue breakdown, retention of potassium may occur rapidly. The serum potassium concentration may reach 8 to 10 milliequivalents per liter. In these instances death in uremia is hastened by the toxic action of potassium on the heart. From a clinical point of view potassium in the food is usually harmless, so long as the uremic patient is in a condition to eat well. But medication containing potassium, which in the past has often been used for treatment of uremic acidosis, may quickly prove harmful.

[*] Possibility of identical excretion of potassium in normal persons and those with uremia but without oliguria.

COMMENT

A final word should be devoted to the principle of repair fluid management. Patients in dehydration have many deficiencies involving both the extracellular and cellular compartments. These include red cells, plasma proteins, water, sodium, chloride, bicarbonate, potassium, phosphorus, amino acids, dextrose and vitamins. Physicians have tended in recent years to attempt massive repair by dumping these constituents into the blood stream by rapid intravenous infusions. Such attempts are based on unsound physiological principles. Utilization by the cells of the proffered constituents is limited by the slow permeability of the cellular membrane and by the disturbance of cellular metabolism produced by intoxication, relative anoxia and alarm reaction.[1a] In addition, such repair is usually initiated when circulation is poor and renal power of selective excretion is limited. Even the repair of the vascular and interstitial compartments must be made at a rate slow enough to avoid overburdening the heart and to prevent the "speed shock" of too rapid a change in the concentration of pharmacodynamically active constituents. In general the quantity and makeup of the intravenous infusions and the order of their administration should be designed to restore vital functions first, such as blood volume, oxygen-carrying power, blood pressure, renal circulation and normal p_H. If such treatment restores consciousness and enables the patient to take fluids and nourishment by mouth, oral alimentation should then become the mainstay of the repair management, particularly with respect to potassium. The use of Ringer's solution instead of istonic sodium chloride solution for the initial injections will at least tend to prevent the dilution of extracellular potassium concentration. If more potassium has to be given intravenously, not more than 2 Gm. of potassium chloride should be present in any liter of venoclysis fluid. No extensive intravenous potassium management should be undertaken unless adequate laboratory facilities are available for quick potassium determinations. In fact, no program of repair management is safe without frequent examinations which include the clinical examination of the patient, determination of the urine volume, specific gravity and p_H, as well as serum analysis for chloride, bicarbonate and, preferably, sodium and potassium.

ABSTRACT OF DISCUSSION

Dr. Helen Eastman Martin, Calif.: Analysis of the etiology of potassium deficits in 150 patients with serum potassium levels under 4.2 milliequivalents per liter, at the Los Angeles County Hospital illustrates all the major mechanisms mentioned by Dr. Hoffman as causing shifts of body potassium. Hypopotassemia, due to either poor food intake or use of nasogastric suction and potassium-free parenteral fluids, developed in 131 of the patients. The average period of time of poor food intake prior to development of a low serum potassium was 16.3 days. Low serum potassium levels developed 5.3 days after institution of nasogastric suction plus 7.5 days of previous poor food intake. Nine of the patients had loss of potassium from the gastrointestinal tract or urine as the major cause of the potassium deficit. Shifts in potassium during treatment of diabetic coma accounted for low serum potassium levels in 10 of the patients. The relation of the acid-base balance was analyzed separately; the importance of alkalosis is seen by the fact that 64 patients had alkalosis. In the last few years my associates and I have treated without difficulty over 500 patients with low serum potassium levels. This includes 50 patients with diabetic coma. Therapy has been mainly by the intravenous route. Dehydration is corrected first, and dilute solutions of potassium salts are given slowly to prevent rapid shifts in the serum level. Concentrated solutions are given only if alarming symptoms, such as muscle paralysis, are present. Such concentrated solutions are administered slowly and cautiously and followed with frequent serum potassium determinations or frequent electrocardiograms. The treatment schedule we have used is as follows: 1. Prophylaxis of potassium deficits (mainly postoperative patients), 3 to 6 Gm. of potassium chloride every 24 hours given intravenously as a 0.1-0.2 per cent solution at rate of 1 liter every one to two hours. 2. Treatment of acute deficits (acute alkalosis, diarrhea), 6 to 9 Gm. of potassium chloride every 24 hours given intravenously as a 0.1-0.2 per cent solution as above. (This includes maintenance dose.) 3. Severe, chronic deficits (mainly surgical patients with loss of gastrointestinal content maintained for days on gastrointestinal suction and potassium-free parenteral fluids), 20 Gm. of potassium chloride every 24 hours given cautiously and intravenously as a 0.3-1 per cent solution or 10 Gm. of potassium chloride every 24 hours intravenously plus 10 Gm. of potassium chloride orally, and 4. Diabetic coma, 2 to 4 Gm. of potassium chloride intravenously as 0.1-0.2 per cent solution. If urine output is adequate, additional treatment with 12 Gm. potassium chloride orally every 24 hours (2 Gm. every four hours) should be started in the second to the fourth hour of coma.

Dr. A. C. Corcoran, Cleveland: Dr. Martin's comments on the value of potassium repletion in the treatment of recovering diabetic coma bring to mind the wisdom of my former chief, Dr. I. M. Rabinowitch, of Montreal, in his routine insistence on the use of salt fat-free broth, 1 cupful every hour on the hour. Some of our visitors seemed to look on this procedure as old fashioned and suggested the substitution of infusions of sodium chloride. However, a favorable clinical course and a low mortality rate prompted Dr. Rabinowitch to maintain his position, and we now find justification for it in the potassium supplied in the broth. The technics of blood chemistry in current use deal only in terms of concentration, whereas the physiology of fluid balance and fluid repletion deals with volumes and contents. It is to be hoped that the technics of the near future may bring to the clinician his guiding answers in terms of fluid compartments. Dr. Hoffman has made valuable contributions to blood chemistry as it exists now. I urge him to participate in this further development. Dr. Darrow has drawn attention to the association of potassium depletion with hypochloremic resistant alkalosis. A recent observation, made in consultation, emphasizes this point. The patient in question had vomited and had a biliary fistula. She had a severe alkalosis and was incontinent and confused. An electrocardiogram, obtained to detect hypopotassemia, was unfortunately mislaid at the outset; the presumption was that this was an alkalosis due to acid loss. A total of 400 milliequivalents of chloride ion as hydrochloric acid was infused during 24 hours. This infusion had effected no substantial change in the patient's clinical condition, in the serum concentrations of chloride and carbon dioxide or in the electrocardiogram. The electrocardiogram was found to show evidence of hypopotassemia. With provision of only 54 milliequivalents (4 Gm.) of potassium chloride, she roused from her coma, her electrocardiogram improved, the serum carbon dioxide substantially decreased and chloride increased to almost normal levels. Thus, an unintentional clinical experiment showed the extreme resistance of the alkalosis in potassium deficiency. In the subsequent nine days the patient received potassium chloride at the rate of 4 to 8 Gm. daily to a total of 40 Gm., or 536 milliequivalents, of potassium. The clinical condition steadily improved. The electrocardiogram was improved but not to normal, and the serum potassium reached a level of only 3 milliequivalents per liter. The patient thus also demonstrated the extreme degree of potassium depletion which may pass unrecognized. Especially does this case emphasize, as do others in the collection of Drs. Proudfit and Ernstene at the Cleveland Clinic, the usefulness of the electrocardiogram in the diagnosis of a hypopotassemic state whenever rapid methods for the determination of serum potassium are not available. Finally, a note on a patient whose renal damage from chronic pyelonephritis made it difficult to excrete not only protein metabolites but the salts which were provided during treatment of dehydration consequent on intestinal obstruction. In this patient the blood urea reached the level of 330 mg. per 100 cc. and the total base 176 milliequivalents during treatment with a mixture of water as 5 per cent dextrose and Ringer's solution in about a 3:1 ratio, liter for liter. A change in the ratio of the fluid repletions to 5 liters of water and 1 liter of Ringer's solution resulted in gradual recession of the blood urea level, an increase in urine volume from 2 to 4 liters, restoration of total base to 140 milliequivalents and progressive improvement with eventual return of the blood urea to nearly normal. Hypertonicity of body fluids due to administration of more electrolyte than this patient could excrete actually increased the existing dehydration and aggravated his renal failure. A urine volume of some 2 liters was in fact inadequate for him, because renal disease increased his minimum effective urine volume. This case demonstrates then the serious effect of relative electrolyte excess and the importance of regulating urine volume, not by rule of thumb but by attention to the level of renal function.

Industry has come to recognize that the toll of death and disability in the management group is excessive. This is evidenced by the report of the Labor Economic Section of General Motors Corporation in 1944[1] that 189 men in that corporation's management group had died in the preceding five years. Realizing that the health maintenance program for the supervisory group had proved inadequate, the corporation set up a program of diagnostic health examinations to prevent this catastrophic loss. The Life Extension Institute reported that of 1,000 holders of life insurance policies in amounts of $25,000 or over who had received extensive examinations since Jan. 1, 1938, of whom 81 per cent were more than 40 years of age, 79 per cent were found to have physical impairments (18.5 per cent of which were high blood pressure and 22 per cent abnormalities of the heart). More recently, Franco[2] reported that periodic health examinations uncovered major medical disease in 25 per cent of executives examined. In *Fortune*[3] for June 1950, there was an article, "Why Executives Drop Dead." It quoted from a report of the Life Extension Examiners of New York that 60 per cent of the executive group examined had conditions requiring a physician's attention, the larger part of them of a cardiovascular nature. In view of the foregoing surveys and others, we should like to present our observations, which may shed light on some disabling factors that, if permitted to go unrecognized, may produce morbidity and mortality of a degree similar to that already reported.

Exhaustion in executives has not been stressed by other investigators in surveys previously published. We became especially interested in this phase of a patient's complaint through our studies on fatigue states as related to a disturbance in carbohydrate metabolism. For many years we have seen young business executives in their early forties or fifties who became utterly exhausted. These executives had many disorders interfering with their efficiency. Apparently they started out in their jobs with all the zest and enthusiasm and ambition to reach a goal which would give them prestige, affluence and security. Most of them were college trained, and many had graduate education preparing them for their life work. Why did men with such drives manifest disabilities at an age at which they should have been most productive? Why did these men live under tension which not only affected them but projected their emotions on employees under their supervision? Why were some departments in industry more productive than others engaged in similar lines of work? Physicians must furnish answers to all these questions if the health

and welfare of executives are to be preserved and if the harmony and safety of their employees are to be guarded at all times.

We therefore undertook a comparative study of the last 50 business executives under the age of 50 who consulted us as patients and of a similar group of executives who were referred to us by corporations for prophylactic examinations.

GROUP OF PATIENTS

The group of executive patients was studied by careful history taking, physical examination and thorough laboratory and roentgenologic investigation to evaluate the clinical picture. It is interesting to note that in 60 per cent (fig. 1) of this group fatigue was one of the outstanding complaints. The evaluation of this complaint is complex, because it is largely subjective and must be evaluated on an individual basis. Heretofore there has not been an objective measurement of this symptom.

In 43.3 per cent (fig. 1) of the fatigued group we found a more rapid disappearance of the sugar from the blood as measured by the three hour intravenous dextrose tolerance test (table 1, fig. 2); in other words, these patients had relative hypoglycemia.

TABLE 1.—*Mean of Blood Sugar Tolerance in 43.3 per Cent of the Fatigued Group*

Time of Test	Blood Sugar Levels, Mg./100 Cc.
Fasting	73.6
½ hr.	118.8
1 hr.	74.8
2 hr.	61.2
3 hr.	56.4

The clinical significance of this has been stressed in previous communications.[4] In 58 per cent of the entire group of executive patients, the third hour blood sugar level was below the initial level, determined during fasting. In some instances there was a drop of 30 to 40 mg. per 100 cc., while in others the drop was between 5 and 15 mg. One severely fatigued executive showed a fasting level of 87 mg. per 100 cc., and at the third hour his blood sugar level had dropped to 44 mg. This relative hypoglycemia has been shown in previous studies to be an effect of overstimulation of the islet cells of the pancreas, mediated by the parasympathetic nervous system via the vagi. Blocking of the vagus nerves with atropine sulfate throughout the 24 hour period has resulted in the elimination of this drop in blood sugar values. Several patients who have had a vagectomy for treatment of peptic ulcer have shown restoration of the intravenous dextrose tolerance curve to near normal. If the autonomic nervous system is involved in this disturbance of function, as these observations suggest, the origin of the disturbance must be in the emotional centers of the central nervous system. The brain is highly susceptible to changes in nutrition. The most important food that the brain uses is sugar. Our studies in fatigue states reveal that when an inadequate amount of dextrose circulates in the blood, the brain does not function properly, the patient becomes high-strung and easily fatigued and the body does not maintain its competence. A more or less constant feature in the life situation of the tired young business executives treated was a loss of zest, loss of enthusiasm and boredom and antipathy for their jobs, business superiors and associates.

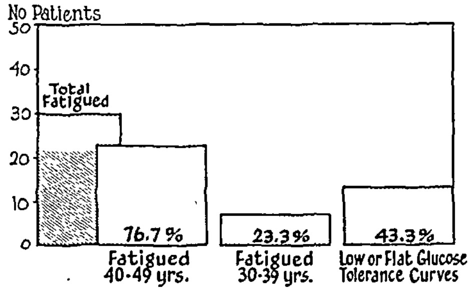

Fig. 1.—Incidence of fatigue in the 50-patient executive group.

Psychological studies have revealed that executives with somatic symptoms are as a rule dependent men whose insecurities and feelings of inferiority are great. Their drives to succeed are a reaction to their intense fears of being inadequate, which are expressed as insatiable ambition, producing somatic symptoms in the gastrointestinal, cardiovascular, respiratory and neuromuscular systems. The executives' interpersonal relations appear adequate on the surface, as far as their business associates are concerned. However, their reaction to their families is frequently hostile, so that their wives and children as a rule are injured. Frenzy and repressed aggression, frequently on an unconscious basis, are present in most such persons, though they manifest strong defenses against expressing their psychological weaknesses. Their capacity for getting pleasure out of life is limited.

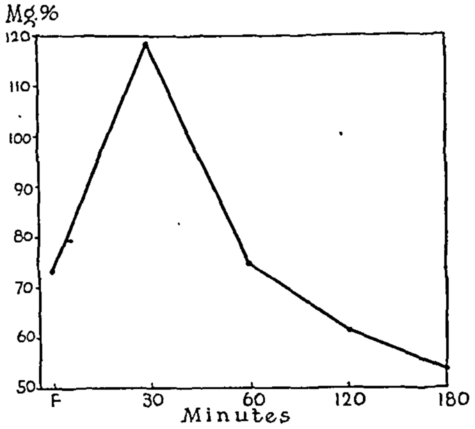

Fig. 2.—Intravenous dextrose tolerance test of the fatigued group. Average of curves of 43.3 per cent of fatigued patients.

Another significant characteristic of the executive's thinking is a fear of failure. Even though the executive can look back with some pride on his accomplishments, there is always apprehension or fear that all will not be the same tomorrow. The fear is not so much of loss of material things as of loss of pride. These psychosomatic manifestations are well illustrated by the following report of an executive patient.

3 hr.	56.4

The clinical significance of this has been stressed in previous communications.[4] In 58 per cent of the entire group of executive patients, the third hour blood sugar level was below the initial level, determined during fasting. In some instances there was a drop of 30 to 40 mg. per 100 cc., while in others the drop was between 5 and 15 mg. One severely fatigued executive showed a fasting level of 87 mg. per 100 cc., and at the third hour his blood sugar level had dropped to 44 mg. This relative hypoglycemia has been shown in previous studies to be an effect of overstimulation of the islet cells of the pancreas, mediated by the parasympathetic nervous system via the vagi. Blocking of the vagus nerves with atropine sulfate throughout the 24 hour period has resulted in the elimination of this drop in blood sugar values. Several patients who have had a vagectomy for treatment of peptic ulcer have shown restoration of the intravenous dextrose tolerance curve to near normal. If the autonomic nervous system is involved in this disturbance of function, as these observations suggest, the origin of the disturbance must be in the emotional centers of the central nervous system. The brain is highly susceptible to changes in nutrition. The most important food that the brain uses is sugar. Our studies in fatigue states reveal that when an inadequate amount of dextrose circulates in the blood, the brain does not function properly, the patient becomes high-strung and easily fatigued and the body does not maintain its competence. A more or less constant feature in the life situation of the tired young business executives treated was a loss of zest, loss of enthusiasm and boredom and antipathy for their jobs, business superiors and associates.

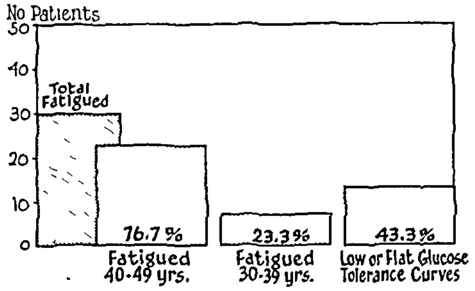

FIG. 1.—Incidence of fatigue in the 50-patient executive group.

Psychological studies have revealed that executives with somatic symptoms are as a rule dependent men whose insecurities and feelings of inferiority are great. Their drives to succeed are a reaction to their intense fears of being inadequate, which are expressed as insatiable ambition, producing somatic symptoms in the gastrointestinal, cardiovascular, respiratory and neuromuscular systems. The executives' interpersonal relations appear adequate on the surface, as far as their business associates are concerned. However, their reaction to their families is frequently hostile, so that their wives and children as a rule are injured. Frenzy and repressed aggression, frequently on an unconscious basis, are present in most such persons, though they manifest strong defenses against expressing their psychological weaknesses. Their capacity for getting pleasure out of life is limited.

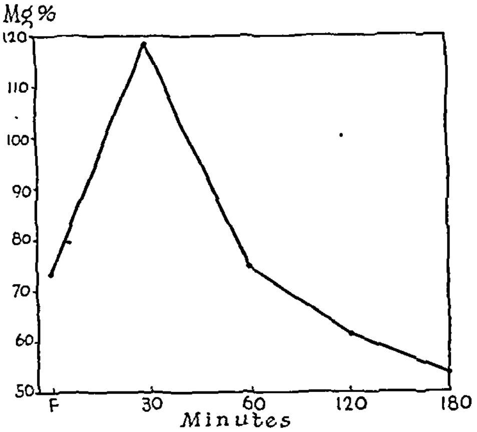

FIG. 2.—Intravenous dextrose tolerance test of the fatigued group. Average of curves of 43.3 per cent of fatigued patients.

Another significant characteristic of the executive's thinking is a fear of failure. Even though the executive can look back with some pride on his accomplishments, there is always apprehension or fear that all will not be the same tomorrow. The fear is not so much of loss of material things as of loss of pride. These psychosomatic manifestations are well illustrated by the following report of an executive patient.

REPORT OF CASE

A business executive, 37 years of age, had felt well until nine days prior to consultation, when at 3:30 p. m., as he was walking through the factory, he suddenly felt light-headed, began to perspire and noticed quickening of his heartbeat. His legs felt weak and he had to sit down. The company physician found his systolic blood pressure at that time to be 110. He was taken to the hospital, where an electrocardiogram and blood count were within normal limits. He remained in the hospital only one hour. However, after that time he continued to feel weak and tired; he became light-headed when up and around but felt normal when lying down. It tired him to walk one block, but he experienced no shortness of breath. He stated that on the day preceding the onset of these symptoms he thought he had overexerted himself. His muscles ached and felt dull, as though they were tired, and he noticed a peculiar sensation over the middle anterior part of the chest. This sensation disappeared almost entirely, yet walking a half block still brought on a "choked-up" feeling.

Physical examination revealed nothing of clinical significance. Except for the intravenous dextrose tolerance test (fig. 3), thorough laboratory and roentgenologic studies gave normal results. The dextrose tolerance curve, however, resembled the so-called "flat curve" which we had previously observed in fatigue patients. This "flat curve" is characterized by a lower than normal level at the half-hour determination and failure of the blood sugar to return to the fasting level in three hours.

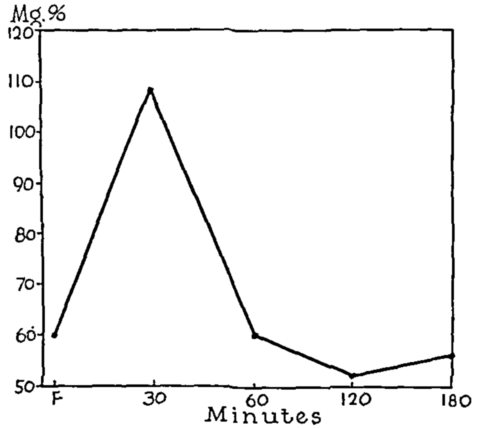

Fig. 3.—Intravenous dextrose tolerance test of patient aged 37.

Because we were interested in discovering what precipitated the acute condition which had persisted for nine days, we inquired into the psychological factors which might have brought about the breakdown. We found that the patient was employed by a concern which had decided shortly after the war that a plant in a small town would be better suited than their current plant to their specifications and purposes. They moved their key employees into a small community, built homes for them and set them to work. For the first few years of operation of this plant, operations went at top speed and with the smoothness of a fine watch. However, after four or five years the management found that efficiency in the plant was lowered. There had been no change in the capabilities of the executives; they were still young and still able to do a job, but they now were becoming tired, befuddled and irritable. The chief executive, at the age of 37, had noticed that in the early midportion of the afternoon he experienced acute fatigue. He began to suffer from precordial distress; he resorted to chain smoking and felt exhausted when he came home at the end of the day. His wife was struggling along with three children and no diversification in her day's work. When she would have liked a break in the monotony of her domestic life, she found that her young husband was content to sit around and recover from the fatigue of his daily efforts in the plant. This furnished a desirable escape mechanism for him. The situation was aggravated by lack of adequate social outlets, since the couple could not become too closely associated with the younger executives because of the danger that such personal relations would be detrimental to efficiency in business.

Analysis of this executive's life situations showed him to have the aggressive, dependent type of personality commonly seen among executives. The patient's mother had died when he was 9 years of age, and he had been passed from one relative to another until his father remarried two years later. He had been a football player and had subsequently married, had three children and become successful, rising to be executive director of a plant employing 400 workers. The onset of his complaint coincided with the development of a fatigue syndrome in his wife, who was distinctly bored and unhappy with life in a small town and who complained bitterly of the lack of social and intellectual diversion.

What does all this add up to? On the one hand, the business of the plant was conducted more efficiently and production costs were lower than in its previous location. On the other hand, at the end of five years its top executives were distinctly bored and tired and sooner or later became inefficient. Of course management and business must get a fair return on their capital investments or they will not be able to enlarge, modernize or expand their plants. But business should realize that highly developed, highly skilled workers must have some chance for diversion in their life outside the plant. This may mean that management may not profitably locate plants in areas where the labor market is good if the price they have to pay is a breakdown in the efficiency of their top executives.

SURVEY OF CORPORATIONS

For comparison with the group of executive patients, we studied 55 executives under the age of 50 who were referred to us by corporations for prophylactic examination. These were subjected to a routine check-up consisting of a careful history of any complaints, previous illnesses, the last time a complete medical examination was made and any facts pertinent to an accurate inventory of any patient. A complete physical examination was made, and deviations from normal were noted. This was supported by the following laboratory tests: Urine and stool analyses, complete serologic study, blood counts with differential, electrocardiogram, 2 meter roentgenogram of the chest to determine the exact size of the heart and condition of the lungs and determination of the basal metabolic rate. After the completion of this routine investigation, each person was interviewed at length, and a life survey was made for pertinent facts leading up to the present job situation. This included questions on early childhood, family environment, education, jobs previously held and reasons for leaving, marital status, home life, home environment, frequency and length of vacations, use of leisure hours, avocation and present position. The study included the subject's relations to superiors, equals and those for whose productivity he was responsible, the number of employees under his supervision and his attitude toward these employees.

Emotional Status.—We were particularly interested in evaluating emotional status in the relationships of the subject's everyday life. Early childhood patterns of many of these persons were found to be factors in the later development of insecurities, which were prevalent and which interfered with their efficiency.

The average businessman, if he is in apparently good health, does not go to a physician of his own volition. Twenty-eight of 55 of the executives included in this study had not had a physical examination within the preceding two years. The predominant reason appears to be that everyone thinks his or her organs are superior, although he knows less about the workings of the human body than he does about an automobile. He does not take into consideration the fact that, although one can get new parts for an automobile, no new parts have been developed for the human machine at the present writing. The intelligent person who has an automobile will take that machine into a service station every one or two thousand miles to have it oiled, greased and checked, but he does not give equivalent care to his own body.

It is apparent that industry has a real stake in the management group, in which it has made a large investment. Moreover, the efficiency of workers is definitely related to the physical and emotional stability of their immediate superiors. Yet how many corporations and companies insist on periodic medical examinations for their executives? Review of the literature reveals that only a small percentage of corporations insist on and provide facilities for periodic medical examinations of their management group.

The executive who knows his job well should be able to work with the ease and precision of a well oiled machine. But the executive who has the ability and is disturbed by some emotional factor finds his efficiency definitely impaired and usually resorts to artificial stimulants to whip up his system; thereby he drives his body beyond the limits of its factors of safety. In the human body the factors of safety are no different from those of steel, wood or any other structural material. A certain load can be tolerated, but beyond the limits of stress the compensatory mechanism no longer functions and the body begins to show wear and tear. A man aged 40 or 50 therefore may find himself in the physiological group of men aged 60 or 70.

Physical Observations.—This survey revealed that 29.1 per cent (fig. 4) of the group had hypertension and 27.4 per cent obesity; electrocardiograms were abnormal in 12.7 per cent and on the borderline in 10.9 per cent. Of the whole group, only 5.4 per cent were considered entirely normal, without any physical defects. These figures compared favorably with those of Lutz,[5] who reported abnormality in 82 per cent of his group of executives. Our survey revealed two important facts: first, the lack of adequate medical study prior to this study, and second, the high incidence of asymptomatic organic disease. Lutz [5] reported also that in 41 of 55 patients with diseases of the cardiovascular system there were no symptoms. Fatigue in our referred group was noted in 10.9 per cent as contrasted with 60 per cent in the patient group. Similar surveys in the literature have not emphasized the factor of fatigue.

ETIOLOGICAL FACTORS

It is our observation that the person whose occupation is largely sedentary and primarily mental usually does not have good eating habits. Many an executive will rush to work without an adequate breakfast, although he is in a field of endeavor in which food is of paramount importance because he is using his brain constantly. Breakfast is one of the most important meals of the day because in the morning most persons have fasted for 12 or 14 hours and because physiological studies have shown only enough dextrose reserve in the body for 12 hours. The executive may find that he becomes a little tired and irritable in the midmorning because of lack of adequate food. His luncheon should be well balanced and not hurried. Frequently in the middle of the afternoon he will find himself growing more irritable, and by 4:00 or 5:00 o'clock he again is tired and restless, and his efficiency is definitely impaired, probably because his luncheon was inadequate. We have previously reported on the relation of fatigue states to accidents, and it has been clearly shown that frequent feedings are necessary for their prevention.

Another factor enters into the picture at this stage. Many an executive becomes a chain smoker because the primary effect of tobacco on the carbohydrate-regulating mechanism is to raise the blood sugar level. Unfortunately, excessive use of tobacco has a secondary effect: it depletes the blood sugar level and causes relative hypoglycemia. This is the reason why chain smokers frequently feel faint and giddy, sometimes even having cold sweats and syncopal attacks. As a rule a chain smoker is irritable, shows evidence of high tension and suffers from wear and tear on the heart muscle not only as an effect of increased tension on the coronary circulation but because the myocardium requires a normal amount of circulating dextrose for its maintenance.

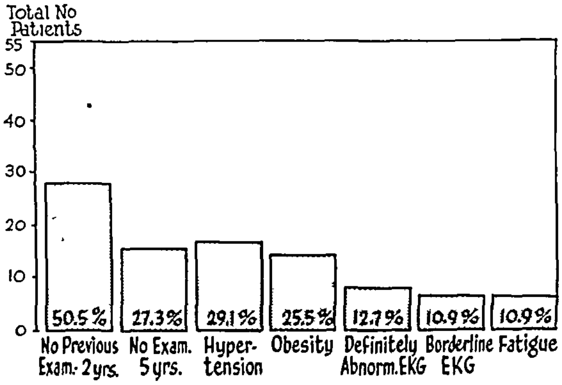

Fig. 4.—Prophylactic corporation survey.

Habein [6] noted that 62 per cent of executives smoke more than a package of cigarets a day, 27 per cent two packages and 21 per cent more than two packages. Raymond Pearl,[7] one of the world's greatest authorities on longevity, has noted that one of five heavy smokers between the ages of 30 and 50 dies before his time.

Finally, at the end of the day, the executive goes to the nearest bar and sits down for several drinks. The sense of well-being that follows a cocktail hour is due to the fact that alcohol tends to stabilize the emotional household by removing cortical inhibitory influences.

TREATMENT

The philosophical approach to the treatment of exhausted executives would naturally entail the eradication of factors which brought on and magnified the fatigue states. Dietary and pharmacologic measures have been employed to normalize the disturbed carbohydrate metabolism. The accompanying diet (table 2) is therefore suggested for patients with uncomplicated fatigue.

To stabilize the disordered carbohydrate metabolism of the exhausted patient, we have used atropine and phenobarbital in suitable doses throughout the 24-hour period, to reduce the effect of parasympathetic stimulation on the islet cells of the pancreas.

[7] Pearl, R., cited by Alvarez, W. C., in Medical Care of Executives, Illinois M. J. 83: 4 (April) 1943.

Since the manifestation of fatigue is in part a psychosomatic problem, one wonders whether affected executives should be treated by psychiatrists or whether their problems may be superficial enough to be handled by their personal physician. If the physician is well enough informed on psychiatric problems, he may point out to the patient the factors which produce the disability, but if the emotional picture is complex and the patient is exceedingly disturbed, a dynamically oriented psychiatrist should be consulted. Many business organizations now hire psychologists as either personnel advisors or industrial psychologists. This is a good form of industrial hygiene.

SUMMARY

Fifty business executives under 50 years of age who sought medical care for various reasons and 55 similar subjects referred by their employers for routine check-up have been compared as to physical condition, laboratory observations, roentgenologic evidence of abnormality and emotional status.

Table 2.—*Suggested Diet for Fatigued Executive*

Foods to include daily:

Cereal and bread	Whole grain or enriched, four servings or more
Meat, poultry or fish	Two servings or more
Eggs	At least three a week
Vegetables	At least two servings a day; one serving or more should be of a green or yellow vegetable
Potatoes	One serving or more
Fruits	At least two servings; one serving should be of citrus fruit or melon; the syrup of canned fruits should be avoided
Milk	One pint or more
Water	Six to eight glasses, which may include coffee and tea
Desserts	Fruit as specified, simple puddings, fruit gelatin, simple cakes (sponge or pound cake without icing), simple cookies
Fats	As needed and desired

Foods to avoid:

Sugar, candy, pie, pastries, jelly, honey, jam, syrup, alcoholic and carbonated beverages

Sample Menu

Breakfast	Luncheon	Dinner
Orange juice	Tomato juice	Chicken broth, rice
Oatmeal	Broiled lake trout	Broiled lamb chops
Poached egg	Asparagus	Baked potato
Toast	Combination salad with dressing	Julienne carrots
Butter	Bread	Perfection salad
Coffee	Fruit cup	Bread
No sugar	Butter	Butter
	Tea or coffee	Baked custard
	No sugar	Tea or coffee
		No sugar

10 a. m. Milk, 6 oz. 3 p. m. Milk, 6 oz.
Bedtime Milk, 6 oz.; crackers, cereal or toast; fruit

Note: The patient may smoke after meals but never on an empty stomach.

Fatigue was one of the outstanding complaints in the group of patients studied. It is often related to a disturbance of carbohydrate metabolism and to faulty dietary habits.

Life situations play an important role leading to exhaustion in executives. A dietary and pharmacologic approach to the therapy of exhaustion has been suggested. The role of alcohol and tobacco has been discussed.

CONCLUSIONS

We present evidence to show that executives do become exhausted. Frequently organic disease may progress unnoticed. The stress and strain of superimposed emotional factors on well balanced organic defects give rise to symptoms which cause the patient to seek medical care.

Industry should insist on periodic health examinations of executive personnel, since asymptomatic organic illness often is disclosed by prophylactic examination. Management also must recognize the need for psychological and psychiatric counseling in guarding the well-being of its executive talent for long term efficiency.

Physicians must approach the problem of disturbed physiological balance with sympathy and understanding. Fatigued patients should not be dismissed with a diagnosis of "functional disease." If the common sense of the family physician of the past is combined with the scientific knowledge of today's laboratory trained physician, it may help to solve some of the problems which confront industry.

104 South Michigan Avenue.

ABSTRACT OF DISCUSSION

Dr W. P. Shepard, San Francisco: To my knowledge this is the first time that we have had pointed out the fatigue syndrome in this type of person. Whether or not we are dealing with a new clinical entity, it certainly is complicated and will need much more investigation. I should like to see a comparison of the occurrence of these symptoms among nonexecutives. I should like to see whether the leaders, foremen and major subordinates may show about the same type of clinical complex, or whether it occurs solely among major executives. Recently there have been studies made of the effect of different company practices on the strain resulting on all employees, including the executives. Among these, Dr. Sawyer has published an interesting summary of vacation practices. We do not know what it is that brings a man to the breakdown point. Although every mechanism, including the human, has a breaking point, it isn't safe to experiment with the human mechanism. Probably we got more data on this subject from the military during the war than any other one place, and we are seeing much the same type of thing in the young executive. We need to have a better way of calibrating man's ability to withstand stress. I hope that this is the start of larger group studies of this kind and that we will eventually have more data on this problem.

Dr. Sidney A. Portis, Chicago: Fatigue is a pleomorphous symptom. Not only is it associated psychologically with factors of security, but for the most part it is seen in persons who suffer from boredom, who lose their zest and enthusiasm. It may develop in unpleasant social situations. It may develop because of the mere thought of doing certain types of work. The average person who is enthusiastic seldom feels tired. In an emergency situation, a person can undergo an unusual emotional strain and expend an unbelievable amount of energy without feeling correspondingly tired. In practically every patient who has a disturbed dextrose metabolism associated with fatigue, as a rule the three hour blood level is below the fasting level, and in many instances there may be a difference as great as 30 mg. per 100 cc. In the series of patients reported in this paper, the average curves were distinctly lower than those seen in a large group of persons previously reported as relatively normal. One can subject a normal person to boredom, and his blood sugar level may drop 10 to 15 mg. per 100 cc. while he is under the influence of that boredom. This observation had been made and reported by previous workers. These exhausted business men were given some insight into their life situations, were put on a suitable diet and were given medicaments as needed, to the end that they did a better job, were more efficient, were happier and, what is more important, lost their fatigue. It is important to have a philosophical approach to this whole problem. These business executives are tired, but this tiredness is not entirely dependent on organic disease. We must recognize that life situations, both within and without business, play an important role. The fatigued executives come to us for help. We must approach their problem with an open mind. Nobody wants to be ill. Nobody is sick unless there is a cause, whether it be functional or organic. Whatever the basis, it is our job as physicians to rehabilitate this group of young business executives in order that they do not lose their efficiency too early in life.

BEDSIDE MANAGEMENT OF PROBLEMS OF FLUID BALANCE

BELDING H. SCRIBNER, M.D.
MARSCHELLE H. POWER, Ph.D.
and
EDWARD H. RYNEARSON, M.D.
Rochester, Minn.

It is our purpose in this paper to describe a practical clinical routine for the accurate determination of water and chloride balance and to demonstrate how such balance data may be employed to determine water and electrolyte dosage in difficult problems of fluid balance.

It is critically important to attempt to maintain normal water and electrolyte balance in severely ill patients. Yet this is often difficult to accomplish in patients with a lowered cardiorenal reserve, acute infection, oliguria, prolonged severe illness or large losses of bowel fluid. In this paper we are concerned with the difficult problem of determining daily salt (sodium chloride) and water requirements in these complicated conditions. The management of such patients is difficult because the usual criteria for determining salt and water needs that may be satisfactory in the routine case are often inadequate when complications are present. There are three reasons for this:

1. Determinations of the concentration of plasma sodium, chloride and bicarbonate are of limited value as a basis for planning fluid and electrolyte therapy because they can be misleading.[1] For example, a patient may be grossly edematous and therefore have too much salt in his body but at the same time have normal concentrations of plasma electrolytes.

2. The most commonly used criteria of salt and water needs are the clinical signs and symptoms of electrolyte imbalance. Though helpful when present, they are inadequate because they are insensitive. Stewart and Rourke [2] have shown that a normal subject may retain 700 milliequivalents of extra sodium chloride without becoming detectably edematous. Yet edema is about the only available clinical sign of sodium chloride overdosage. Others have found that a normal subject may lose 600 milliequivalents of sodium chloride before depletion of electrolytes becomes detectable by clinical observation.[3] Thus the total body content of sodium chloride can fluctuate over a range of as much as 1,300 milliequivalents without its being apparent clinically. Fluctuations of this magnitude might be harmful to severely ill patients.

3. Serial determinations of body weight, a sensitive index of fluctuations in total body water, give no direct information about changes in the amount of sodium and chloride in the body because large fluctuations in the amount of intracellular water also occur.[4] What is more important, it is often impractical to weigh severely ill patients, especially if they are in the postoperative period.

There is, therefore, a need for more exact methods of determining the daily requirements of water and electrolyte in patients with complicated problems of fluid balance. To meet this need a new approach to the clinical management of parenteral fluid therapy has been devised. This approach is based on the accurate measurement of the intake and output of chloride. The aim of parenteral salt and water therapy is to maintain the total amount of salt and water in the body at a normal or desirable level. Since this level will be maintained if the intake of water and salt equals the output, an accurate measurement of the output of these substances can be used as a basis for planning intake. Furthermore, the difference between the intake and output of chloride —that is, the chloride balance—is an absolute measure of changes in the total body chloride. Therefore the chloride balance is a reasonable basis for detecting fluctuations in the amount of salt in the body that are not detectable by the other methods previously mentioned. Because of this, the determination of chloride balance has been used as a tool in the clinical investigation of electrolyte metabolism.[5]

The application of chloride balance technics to the clinical management of problems of fluid balance has not been practical in the past because of the expense and technical difficulties of obtaining chemical determinations. However, a new method for the rapid, accurate determination of chloride at the bedside makes the measurement of chloride balance a practical clinical procedure.[6] The method is based on the direct titration of the chloride with mercuric nitrate. The end point is a sharp purple color that is easily seen. Reagents are stored in small bottles which are taped together to form a portable test set. Solutions are measured with tuberculin syringes which fit into the caps of the bottles. Results of determinations are read directly from the scale of the syringe and are available within about a minute after specimens are obtained. Duplicate determinations on plasma agree within plus or minus 1 per cent. Nearly comparable accuracy is possible on other fluids, such as urine or liquid stool. Results obtained by the bedside method compare favorably with those obtained by standard chloride methods. The accuracy of the determination may be checked at any time, since a bottle of standard salt solution is included in the test set.

METHOD FOR DETERMINATION OF WATER-CHLORIDE BALANCE

Accurate determination of the intake and output of water is often difficult and sometimes discouraging. The fact that the chloride balance can now be determined simply, provided the intake is known and the specimens of excreta are accurately saved, creates a new need for a practical hospital routine for obtaining accurate data on intake and output. A routine has been evolved that seems to meet this need. The routine is a definite departure from the usual nursing procedure of collecting, measuring, discarding and recording of each specimen. Rather, all excreta are saved by the nurses in labeled containers and are later measured and analyzed for chloride at the bedside by the physician or other person conducting the study. The routine also provides a double check on the determination of water and chloride intake.

The reliability and usefulness of the balance data obtained by this routine will, of course, depend directly on the completeness of collections of specimens and the accuracy of charting

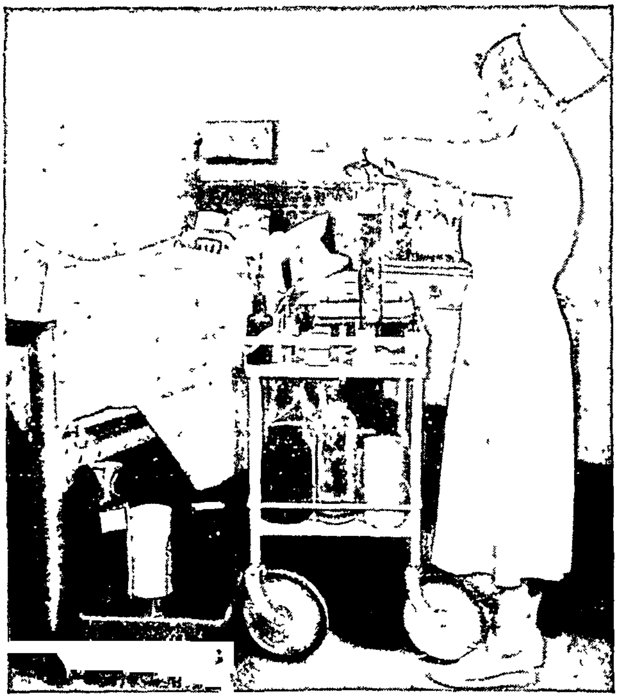
(*b*) Since a description of the bedside chloride method was published, it has been found advisable, when making up the mercury reagent, to use double the quantities of concentrated nitric acid originally suggested.

of intake by the nurses. The importance of their part in the study should be emphasized by pointing out that the treatment and therefore the welfare of the patient depend directly on the reliability of their work. It also can be emphasized that this nursing routine involves less work than does the old method of determining intake and output.

The routine will work only if there is close cooperation between the nursing staff and the person conducting the study. The duties of each should be clearly delegated; the nurses should be carefully coached and given a written summary of their duties.

Duties of the Nursing Staff.—1. All excreta are saved in clearly marked containers[7] which are supplied by the person conducting the study. Since that person will measure the specimens, the nurses are relieved of the unpleasant task of charting and totaling outputs. To insure that all specimens are saved it is helpful to affix a sign over the patient's toilet directing that nothing be discarded.



A fluid balance technician is shown analyzing a specimen of gastric fluid for chloride. She is in the process of completing a water-chloride balance sheet on this patient. The cart is used to transport containers It also serves as a place to work

2. If specimens are lost either through incontinence or by being discarded by mistake, the nurse must make an estimate of the volume of fluid lost and note it on the record. Although such estimates are rough, they have proved sufficiently accurate to be used to complete the balance study. However, losses through incontinence must be kept at a minimum if the data are to be reliable, and every precaution should be used to avoid such losses. Uretheral catheters should be used for patients with urinary incontinence. Collection cups, continuous suction devices and tubes can be employed to make collections from gastrointestinal fistulas fairly complete.

3. Frequent notations on the amount of visible perspiration should be made. If the bedclothes are changed because of sweating this should be noted. These notes form the basis for the estimate of insensible loss.

4. Complete charting of the type and amount of all parenterally administered fluids is essential. As a double check, all empty parenteral fluid bottles are saved to be checked later by the person doing the balance study.

5. The nurses should keep as accurate an account as possible of oral intake of fluid and food. A graduated cup or glass aids in determining the oral intake of fluids. The help of the patient or his relative should be enlisted in keeping an accurate account of oral intake.

6. Fluid used to irrigate suction tubes may be taken from a graduated liter bottle supplied and refilled by the person conducting the study. This obviates charting of irrigation volumes by the nurses. Irrigation returns are simply mixed with the other aspirate.

Duties of the Fluid Balance Technician.—The person conducting the study who supplies the containers and completes the determination of water-chloride balance is known as the fluid balance technician. In small hospitals where there is only an occasional patient requiring such studies, the physician or intern may himself act as the fluid balance technician. In larger hospitals it may be advisable to organize a hospital fluid balance service and train a person, preferably a nurse, to be a fluid balance technician. This is not difficult because the bedside chloride test used to analyze the specimens is simple and requires no prior knowledge of chemistry. Nurses so trained have capably carried out the duties of the fluid balance technician in the hospitals in Rochester, Minn. In one 1,000 bed hospital where perhaps 100 major surgical procedures a week are done, the number of patients on the fluid balance service averages 15 to 20 at any one time. The fluid balance technician, using a hospital cart as a table, (see the illustration) visits each of these patients each day and performs the following duties:

1. The technician accurately measures the volume of all excreta that have been saved. Each specimen is then analyzed for chloride by the bedside method[6a] and for p_H by the use of indicator paper.[8] Results are assembled, calculated and then recorded on a form such as that shown in table 1. This form is known as a water-chloride balance sheet. The total chloride output is calculated by multiplying[9] the concentration of chloride in the specimen by the total volume.

2. The technician totals and enters in the output column an estimate of all losses through spillage and incontinence as determined from the nurses' notes. An example of such an estimate is the "Estimated urine lost" entry in table 1. For the purpose of calculation, the chloride concentration and the p_H of the specimen lost are assumed to be the same as those of the specimen saved and analyzed

3. Insensible and sensible losses of water and chloride are estimated on the basis of the amount of visible perspiration as noted in the nurses' notes and as determined by questioning the patient. The estimates are made according to the schedule shown in table 2. This schedule has been drawn up tentatively and is based on the literature[10] and on limited experience in the estimation of insensible loss from serial weighings of the patient.[11] The values for chloride in sweat are based on the data of McCance[12] and others[13] They are intended only as approximations, since the chloride content of sweat varies widely; the chloride estimates are, if anything, too high, especially in the case of patients who are acclimatized to a hot environment.

We have had no experience with the determination of sensible and insensible loss at high environmental temperatures Under such conditions our schedule may have to be revised upward because, in dry climates especially, a patient may sweat continually without its being apparent to him or his nurse Wiley and Newburgh[14] estimate that when the environmental temperature is above 30 C. the insensible loss of an average man may increase about 500 ml. of fluid per twenty-four hours for every 1 degree Centigrade rise in environmental temperature.

The insensible loss actually may be determined by using water balance data and daily weights.[11] Sometimes a gross underestimate of the insensible loss can be detected from the balance sheet if it shows an unexplained water retention in the presence of a normal volume of urine.

4. Parenteral intake of water and chloride is determined by comparing the nurses' notes with the labels on the empty parenteral fluid bottles that have been saved. The volume, type of fluid and chloride content, including added salts such as potassium chloride, are recorded in the intake column of the balance sheet.

5. The oral intake of water is determined from the nurses' notes. By assuming that food is 100 per cent water, the calculation is simplified. The error introduced by this assumption is small and is usually roughly canceled by the daily water of oxidation, which is also neglected.

6. If it is desired that chloride balance be studied on patients getting a large part of their intake by mouth, it is possible to estimate with sufficient accuracy the oral intake of chloride. Simple broths and tube-feeding formulas may be analyzed directly by the bedside method.[6a] The chloride content of food can be obtained from dietary tables or, if salt is added in cooking, from the dietitian. Salt added by the patient may be determined by having him use a salt shaker made from a Sanford-Magath hematocrit tube. (A perforated paper held over the end with a rubber band converts such a tube to a satisfactory salt shaker.) By weighing the amount of salt in a tube, the number of milliequivalents of chloride that is represented by each division on the scale of the tube may be determined. For common table salt this figure averages about 2.2 milliequivalents per division. By noting the number of divisions the level of the salt falls each day, the number of milliequivalents of chloride used by the patient is determined easily. Although such methods are crude they have proved accurate enough in practice to yield satisfactory results when the chloride balance of normal patients eating a full diet was determined.

TABLE 1.—*Water-Chloride Balance Sheet*[*]

From: 8:00 a. m. Feb. 5, 1950. To: 10:00 a. m. Feb. 6, 1950. Equals: 26 hr.

Intake			Output				
					Chloride, mEq.†		
Volume, Ml.	Fluid	Chloride, mEq.†	Volume, Ml.	Fluid	Per Liter	Total	pH
1,100	Oral	21	1,150	Urine	35	40	6.0

			100	Formed stool	..	0§	...
6,100	Totals	471	5,190	Totals	..	254	...

Daily balance: Water: + 910 ml. Chloride: + 217 mEq. Cumulative chloride balance: + 196 mEq.

---

[*] At the beginning of the period on Feb. 5, 1950 the plasma bicarbonate measured 29 milliequivalents per liter, and the plasma chloride measured 98 milliequivalents per liter; the cumulative chloride balance was minus 21 milliequivalents.

[†] It has been found that the chloride data are most useful when expressed in milliequivalents because this facilitates the indirect estimation of sodium balance (100 milliequivalents of chloride equals 5.85 Gm. of chloride as sodium chloride or 3.46 Gm. of chlorine). However, if one prefers to express chloride as grams of sodium chloride or grams of chlorine, the bedside chloride test can be adjusted to provide results directly in any of these units of measure.[6a]

[‡] It has been found that 150 milliequivalents per liter is a satisfactory figure to employ in calculating the chloride in 0.9 per cent saline solution or similar solutions. If the amount of chloride in a solution is unknown, it may be determined directly by analysis using the bedside method.[6a]

[§] The amount of chloride in formed stool is so low that it can be ignored.

7. The time interval covered by the data in the balance sheet should be indicated at the top of the form as shown in table 1.

8. When possible, the fluid balance technician should weigh the patient daily. A portable bathroom scale calibrated in kilograms may be used. This can be carried right on the cart.

9. When all the items in the intake and output columns have been recorded, the columns are totaled and the balances calculated.

As shown in table 1, the daily balances of water and chloride are simply the differences between the intake and the output. The cumulative chloride balance is the sum of the daily chloride balances and represents the net gain or loss of chloride by the patient since the beginning of the study. In table 1, for example, the cumulative chloride balance on Feb. 6, 1950 is determined by adding the daily balance, plus 217, to the previous cumulative balance, minus 21 milliequivalents, which gives a result of plus 196 milliequivalents. This means that the total amount of chloride in the patient's body is 196 milliequivalents more than on the day the study was started.

When the detection of fluctuations in total body water is important, as in the management of acute renal shutdown, the cumulative water balance may be calculated. However, serial determination of body weight is a more reliable measure of fluctuations of total body water and therefore should be done whenever possible.

Cost and Accuracy of Water-Chloride Balance Studies.—It takes on the average about one-half hour per patient per day for the fluid balance technician to complete a water-chloride balance study. If the study is done by a regular technician working part time or full time on a hospital fluid balance service, the information can be supplied at an actual cost of about $1 to $2 per patient per day depending on the number of patients being studied. Water-chloride balance studies often more than pay for themselves by reducing the number of plasma electrolyte studies.

In the absence of excessive incontinence and continuous sweating, water-chloride balance studies obtained in the manner outlined are surprisingly accurate. We have followed the balances of patients for as long as a month or six weeks with a cumulative error in chloride balance of less than plus or minus 50 milliequivalents per week. When patients are getting a full oral intake, the accuracy is probably about plus or minus 100 milliequivalents per week. If the patients become grossly incontinent, the accuracy may be so low that the study becomes of little value. The accuracy of the chloride balance is due in part to the fact that in the type of patient studied errors made in the estimation of oral intake and insensible loss affect the calculation of chloride balance relatively little.

TABLE 2.—*Schedule for Estimating the Insensible and Sensible Loss of Water and Chloride*

	Water and Chloride Lost in 24 Hr.	
Amount of Sweating	Water, Ml.	Chloride, mEq.
No fever and no sweating	1,000	0
High fever or moderate sweating	1,500	35
Severe sweating (enough to necessitate change of pajamas)	2,000	70
Repeated severe sweating	Higher volumes of water and 70 mEq. of chloride for every 1,000 ml. in excess of the first 1,000 ml.	

MAINTAINING NORMAL WATER AND ELECTROLYTE BALANCE

For reasons to be discussed, it is far simpler to use water-chloride balance data as a basis for maintaining normal fluid balance than for correcting disturbances of fluid balance. Therefore it is important to start a balance study before trouble develops—i. e., on the day of operation for any patient who might be prone to have postoperative complications. To maintain normal water and electrolyte balance in a patient who is normal at the start of treatment, one plans to give the equivalent of the anticipated loss and at the same time to correct the previous day's imbalances.

Anticipating Losses.—Urinary Loss: An allowance of 1,500 ml. of water and 50 milliequivalents of chloride is made for urinary output. These amounts are chosen to provide the kidney with an opportunity to excrete waste products efficiently[15] and to help maintain electrolyte balance. Furthermore, such allowances enable the kidney to correct mistakes that may be made in anticipating other losses. For example, if 500 ml. too little water is allowed for insensible loss, the kidney can correct this error by decreasing the volume of urine from 1,500 to 1,000 ml. without impairing its efficiency.

These allowances for urinary output often have to be modified in the individual case. For example, one would not provide for a urinary output of 1,500 ml. in a case of anuria due to renal shutdown but in another case it might be necessary to allow for higher values than 50 milliequivalents of chloride if the kidneys could not conserve salt.

Insensible Loss: Water and chloride losses are anticipated on the basis of the schedule given in table 2.

Gastrointestinal Losses: By noting the volume of the gastrointestinal fluid lost during the preceding period, one can estimate roughly the volume that will be lost during the next period. For example, if the water-chloride balance sheet indicates that 1,000 ml. of gastric fluid containing 90 milliequivalents of chloride was aspirated during a 12 hour period, one can then estimate that roughly 2,000 ml. of gastric fluid and 180 milliequivalents of chloride will be lost during the succeeding 24-hour period. Such estimates are only tentative, and treatment that is based on them should be revised if the output changes during the period.

The anticipated losses of water and chloride are then totaled. This total represents approximately the amount that should be given in order to keep up with the losses and thereby maintain the status quo. However, it is not necessarily the amount that should actually be given; the previous day's imbalances also must be corrected.

Planning Treatment for the Next Period.—Amount of Water: The general principle consists of noting the volume of the anticipated loss and then planning to give this amount or more, depending on whether or not the patient has a water deficit at the beginning of the period. The presence or absence of a water deficit may usually be determined by noting the presence or absence of thirst and the volume of urine.[3a] It should be noted that the figure for daily water balance is not used as a basis for determining water dosage except in cases of renal shutdown.

Amount of Sodium Chloride: Except as will be noted below in the discussion of acid balance and of sodium balance, the sodium balance is assumed to parallel roughly the chloride balance. Therefore, most losses of chloride are replaced with sodium chloride.

Thirst and oliguria give early warning of disturbances of water balance. Because there are no comparable early signs of sodium chloride imbalance, the amount of sodium chloride in the body can fluctuate through a range of several hundred milliequavalents without its being apparent clinically, as has already been demonstrated. Since the cumulative chloride balance is a measure of changes in the total amount of sodium and chloride in the body and therefore of these very fluctuations, it is used to help determine how much sodium chloride should be given.

The general principle of planning the amount of sodium chloride to give consists of noting the anticipated loss and then planning to give this amount and more or less, depending on the cumulative chloride balance. If the cumulative chloride balance shows a retention of chloride relative to the amount present at the start of treatment when the patient was normal, then less than the anticipated loss of chloride should be given. If the cumulative chloride balance shows a loss, then more than the anticipated loss of chloride should be given. The following case illustrates how normal water and electrolyte balance may be maintained in a patient who is normal at the start of treatment.

A man aged 64 with a chronic duodenal ulcer and hypertension had a partial gastric resection on Feb. 2, 1950. A water-chloride balance study was started on the day of operation because the patient had a lowered cardiac reserve as a result of hypertensive heart disease. The patient was eating a full diet prior to operation and was therefore considered to be in normal balance with respect to water and electrolytes.

His postoperative course was essentially uneventful until February 5, the third postoperative day. About noon on that day he began to have abdominal distention and had to have repeated gastric aspirations. The water-chloride balance sheet for that period and the pertinent blood analyses are shown in table 1. The procedure for planning treatment for the next 24 hours, that is, from 10:00 a. m. February 6 to 10:00 a. m February 7, was as follows:

1. It was anticipated that 1,500 ml. of water and 50 milliequivalents of chloride would be lost in the urine.

2. Since sweating or fever was not anticipated, an allowance of 1,000 ml. of water and no chloride was made for insensible loss.

3. Since 2,840 ml. of fluid containing 210 milliequivalents of chloride was aspirated from the bowel during the preceding 26 hours, it was estimated that roughly 2,500 ml. of fluid containing approximately 185 milliequivalents of chloride would be aspirated during the next 24 hours.

4. Then, by addition, the total anticipated loss was determined to be 5,000 ml. of fluid and 235 milliequivalents of chloride.

5. Since there was absence of thirst on February 6, and since the urinary volume was 1,150 ml., for the preceding 26 hours, it was concluded that a water deficit did not exist. Therefore, a reasonable amount of fluid for the next 24 hours would be 5 liters, the anticipated loss. The amount of sodium chloride this fluid should contain was determined as follows:

6. Since the anticipated loss of chloride was 235 milliequivalents and since the patient had 196 milliequivalents more of chloride in his body than he had on the day of operation when he was presumed to have a normal amount, the administration of only 39 milliequivalents of chloride (235 minus 196) was indicated to restore the total chloride in the body to normal. This amounted to just 260 ml. of 5 per cent dextrose in normal saline solution. Practically, the amount was so small that sodium chloride was not given during the next period. The planned intake, therefore, consisted of 5 liters of dextrose in distilled water, without the addition of salt. It should be

[15] Gamble, J. L.: Chemical Anatomy, Physiology and Pathology of Extracellular Fluid: A Lecture Syllabus, ed. 5, Cambridge, Mass., Harvard University Press, 1947, charts 49 and 17-F.

remembered in this connection that the accumulation of chloride in the body is undesirable for any postoperative patient, especially if the cardiac reserve is lowered.[16]

The plan in the foregoing case was tentative and was subject to modification by changes in output during the period, such as might occur as a result of increased sweating or cessation of gastric aspiration.

Errors in Planning Treatment.—Because the volume of urine and the cumulative chloride balance are exceedingly sensitive indexes of water and electrolyte imbalance, early detection of errors in treatment is possible. In planning treatment from day to day one need not be overly concerned about the exact amount and type of fluid to give, as long as the previous day's imbalances are taken into account. In the case just presented, the patient probably would have had to retain 400 to 600 milliequivalents of chloride (that is, to have a cumulative chloride balance of plus 400 to plus 600 milliequivalents) before the excess could be detected clinically. Similarly, this patient would have had to lose up to 600 milliequivalents of chloride before a depletion would be evident clinically. Therefore, in planning the next day's salt intake it made little difference whether 1 liter of salt solution or no salt solution was given, just as long as the previous day's excess of plus 196 was being corrected by giving less than the anticipated output of 235 milliequivalents. By using this scheme of trying to correct the previous day's imbalances without stopping to ponder over the exact amount of salt and water to give, planning treatment from day to day is simplified and merely involves a glance at the balance sheet and a few rough mental calculations. At the same time this scheme insures that the patient's water and electrolyte balance will fluctuate much more closely around the norm than when the usual methods of planning treatment are employed. This last point is emphasized by the following:

> Two postoperative patients with new ileac stomas posed difficult therapeutic problems because of large losses of bowel fluid. Both patients were studied by water-chloride balance technics, but only in the second case were the data available to the physician treating the patients. Salt and water dosage in the first case was determined by the usual methods. During a seven day period the total body salt in the first case, as measured by the cumulative chloride balance, fluctuated through a range of 1,100 milliequivalents. Only at the extremes of fluctuation was the disturbance evident clinically. During a similar difficult period of management, the body salt in the second case fluctuated through a range of less than 300 milliequivalents.

Disturbances of Acid-Base Balance.—In planning treatment to maintain normal fluid and electrolyte balance, disturbances of acid-base balance often can be anticipated by noting the p_H of the fluids being lost from the bowel. For the purpose of this discussion, a disturbance of acid-base balance is defined as a deviation from normal in the concentration of serum bicarbonate. Only disturbances caused by loss of gastrointestinal fluid are considered here.

Disturbances of acid-base balance result when the intake and output of sodium do not parallel that of chloride. Since preliminary experience indicates that the amount of sodium in a specimen of fluid from the bowel can be estimated roughly from the amount of chloride in that specimen if the p_H is known also, one often can tell from the balance sheet alone whether or not large losses of fluid from the bowel will disturb the acid-base balance. This is done on the basis of the following tentative criteria, which are founded on limited clinical experience and the analysis of 50 specimens of bowel fluid for sodium, chloride and p_H.

If the p_H of the gastrointestinal fluid lost is less than 5, enough more chloride than sodium may be lost to cause an alkalosis; if the p_H is 5 or more but less than 7, no disturbance of acid-base balance is likely to occur; and if the p_H is 7 or more, acidosis may develop, although this has been comparatively rare in our experience to date. The following case illustrates the principles of determining whether large losses of fluid from the bowel will disturb the acid-base balance:

TABLE 3.—*Water-Chloride Balance Sheet in a Case in Which the Acid-Base Balance Was Disturbed**

Dec. 7, 1949: Cumulative Chloride Balance: — 101 mEq. From: 9:00 a. m. Dec. 7, 1949. To: 8:00 a. m. Dec. 8, 1949. Equals: 23 hr.

Intake			Output				
					Chloride, mEq.		
Volume, Ml.	Fluid	Chloride, mEq.	Volume, Ml.	Fluid	Per Liter	Total	p_H
2,540	Oral	60	1,200	Urine	40	48	7.0
1,000	5% dextrose in normal saline	150	1,000	Insensible	..	0	...
1,000	5% dextrose in water	0	3,100	Duodenal fistula	94	307	1.5
4,540	Totals	210	5,300	Totals	..	355	...

Date: Dec. 8, 1949. Daily balance: Water: — 760 ml. Chloride: — 145 mEq. Cumulative chloride balance: — 249 mEq.

* At the beginning of the period on Dec. 7, 1949 the plasma bicarbonate measured 29 milliequivalents per liter, and the plasma chloride measured 99 milliequivalents per liter. At the end of the period on Dec. 8, 1949 the plasma bicarbonate measured 35 milliequivalents per liter and the plasma chloride measured 89 milliequivalents per liter.

> A woman aged 40 who was being treated for a duodenal fistula had for several days received fluids only parenterally. On Dec. 7, 1949 the values for plasma electrolytes were in the normal range (table 3). On that day administration of water and a clear liquid diet was started by mouth. The water-chloride balance sheet for the first day on oral intake showed that the fluid from the duodenal fistula, which had previously been neutral, had now become extremely acid as indicated by a p_H of 1.5 (table 3). This change in p_H may have been due to the fact that the large oral intake stimulated gastric secretion and washed gastric juice down into the duodenum and out through the fistula. The p_H of 1.5 of this fluid suggested that more chloride than sodium was being lost. In this case, the sodium in the aspirated duodenal fluid was actually determined and proved to be 53 milliequivalents per liter as compared with a chloride concentration of 99 milliequivalents per liter. It was therefore reasonable to anticipate that an alkalosis might develop. This was confirmed by a rise in the plasma bicarbonate content to 35 milliequivalents per liter on Dec. 8, 1949 (table 3).

If a disturbance of acid-base balance is anticipated, the concentration of serum bicarbonate can easily be determined to settle the question.[17] To prevent and treat disturbances of acid-base balance, enough sodium and chloride should be given to insure spillage of these electrolytes in the urine. The kidney then can help correct the disturbance by excreting an excess of either sodium or chloride, depending on the need. The correction of disturbances of acid-base balance can be hastened by varying the proportion of sodium to chloride in the replacement fluid.[18]

Sodium Balance Versus Chloride Balance.—One criticism of the proposed technic is that it is concerned with chloride balance when actually it is sodium balance that is important. This criticism may be answered as follows:

1. For the purposes of planning treatment it is assumed that sodium balance must roughly parallel chloride balance or gross disturbances of acid-base balance will occur; as we have already indicated, the proposed technic anticipates disturbances of acid-base balance. In some 300 patients no instance of electrolyte imbalance has resulted from treatment based on this assumption.

2. Although it is true that the amount of extracellular fluid in the body is determined largely by the sodium balance, chloride, like mannitol, is actually a better substance with which to measure the extracellular fluid, because chloride is more completely excluded from the cells than is sodium.[19]

RESTORING NORMAL WATER AND ELECTROLYTE BALANCE

Excluding disturbances of acid-base balance, which have already been considered, and disturbances of potassium and other intracellular ion balances, which will not be discussed in this paper, disturbances of water and electrolyte balance can be classified into four types[20]: (1) dehydration from deficit of water; (2) overhydration from excess of water; (3) dehydration from deficit of sodium chloride, and (4) overhydration from excess of sodium chloride. These disturbances are not seen often in pure form but are usually seen in combination. However, for the purpose of description they are considered separately.

Dehydration from Deficit of Water.—This condition is defined as a loss of water without an associated loss of electrolytes. The body fluids therefore become hypertonic. The condition is suggested clinically by the presence of oliguria and thirst. The deficit is treated by giving enough extra water to alleviate the thirst and to increase the volume of urine. Depletion of water should be treated with caution if the patient is also severely depleted of sodium chloride; the latter condition should be treated at the same time. It is important to exclude primary renal shutdown, such as is seen in lower nephron nephrosis, as a cause of oliguria before administration of extra water is begun. Primary renal shutdown sometimes may be excluded if there is no evident cause for it and if the history, symptoms and laboratory data (including a high urine specific gravity) support the diagnosis of depletion of water. In case of doubt, water should be given cautiously until the volume of urine increases or until it becomes apparent that the oliguria is of primary renal origin.

Overhydration from Excess of Water.—This condition is defined as a relative or absolute increase in the body water without an associated increase in body electrolyte. The body fluids therefore become hypotonic because of dilution. Water excess is relatively infrequent. It usually results from the excessive administration of water to a patient who is unable to eliminate the excess through the kidneys.[21] The severe form of water excess produces the syndrome of water intoxication.[22] Treatment consists of stopping the administration of water. This is about the only condition in which the anticipated loss of water should not be replaced. Treatment with hypertonic salt solution also has been advocated.[23]

Dehydration from Deficit of Sodium Chloride and Overhydration from Excess of Sodium Chloride.—These conditions are defined as a decrease or increase, respectively, in the total body sodium and chloride. There is usually a corresponding change in the total body water so that the concentration of sodium and chloride remain near normal and isotonicity is maintained. However, in severe depletion low levels of serum electrolyte are found. A deficit of sodium chloride is characterized clinically by mental apathy, decreased skin turgor, circulatory collapse, hemoconcentration and low concentrations of electrolyte in the plasma and urine. An excess of sodium chloride is suggested by edema.

The problem of diagnosing and treating depletion and excess of sodium chloride is often difficult because, as stated previously, the clinical and laboratory signs of sodium chloride imbalance are often misleading or insensitive. The cumulative chloride balance is helpful but only in an indirect way, because it measures only changes in the total amount of sodium and chloride in the body, rather than the absolute amount present. During treatment it is difficult to decide when the patient has attained a normal or desirable amount of sodium and chloride in his body. Of course, the easiest solution to this problem is to start with a patient who has normal water and electrolyte balance; hence the importance of starting a water-chloride balance study before trouble develops, as was done in the case depicted in table 1. In most cases, however, one is forced to begin treatment when sodium chloride balance is already greatly disturbed. A general approach to the problem of deciding when the amount of sodium and chloride in the body has been restored to a desirable level is outlined below.

1. At the start of treatment a rough preliminary estimate of the magnitude of the deficit or excess of sodium chloride is made on the basis of the history, physical examination and laboratory data. In illness of short duration comparison of the body weight at the time with the patient's normal body weight may be helpful in making this estimate. From this estimate a preliminary guess is made of the figure which represents the "desirable cumulative chloride balance." The desirable cumulative chloride balance is defined as the value for the cumulative chloride balance that exists when the total body sodium chloride is at a normal or desirable level. In other words, it is an estimate of the gain or loss of chloride that must be effected by treatment to restore the total body chloride of the patient to normal. For example, a patient is definitely but slightly edematous over the sacrum and ankles on the day a water-

chloride balance study is begun. Because of the edema, one may conclude that the total amount of sodium and chloride in the body is well above normal. Since the cumulative chloride balance is always assumed to be zero at the start of a study, in this patient it will be minus several hundred milliequivalents when the amount of sodium and chloride in the body has been returned to normal. The preliminary estimate of the desirable cumulative chloride balance in such a patient might be minus 600 to minus 800 milliequivalents. (The desirable cumulative chloride balance would, of course, be zero in a patient who was normal at the start of this study.)

2. Treatment of the sodium chloride imbalance is begun by giving more or less than the anticipated loss of chloride, as the case may be. When giving more than the anticipated loss of chloride it is sometimes advisable to give more than the anticipated loss of water, because part of the retained salt will hold water with it. As treatment proceeds, an attempt is made to correlate changes in the signs and symptoms of electrolyte imbalance with changes in the total body salt as measured by the cumulative chloride balance. In this way the estimate of the desirable cumulative chloride balance can be made more accurate. For example, if a patient is being treated for a salt depletion and the obvious signs of the depletion (including poor skin turgor, hemoconcentration and low concentration of plasma electrolytes) disappear when the cumulative chloride balance reaches plus 600 milliequivalents, one can usually conclude that the desirable cumulative chloride balance is somewhere around plus 1,000 milliequivalents.

One way to help determine the desirable cumulative chloride balance is to correlate changes in the concentration of chloride in the urine with changes in the cumulative chloride balance. The concentration of chloride in the urine often falls to low levels (that is, below 35 milliequivalents per liter) with the development of only a slight deficit of sodium chloride and rises again only after the deficit has been alleviated.[3a, c] If the urinary chlorides rise from 10 to 70 milliequivalents per liter while the cumulative chloride balance rises from plus 1,100 to plus 1,200 milliequivalents, the desirable cumulative chloride balance is likely to be around plus 1,200 milliequivalents.

Data on urinary chlorides are by no means infallible, and conclusions drawn from them are valid only in the absence of contradictory evidence based on the cumulative chloride balance and over-all clinical evaluation of the electrolyte status. We have found, as have Randall, Habif and Lockwood,[24] that certain severely ill patients can have a high excretion of urinary chloride in the presence of severe salt depletion and vice versa. However, this does not mean that treatment based on the test for urinary chloride is dangerous and misleading. When interpreted as outlined above, limitations of the test are obviated and it has proved to be of great value in helping to determine the desirable cumulative chloride balance. It is hoped that on the basis of further experience with this new clinical tool, the cumulative chloride balance, new principles can be evolved that will simplify the problem of determining the desirable cumulative chloride balance in the individual case.

The fact that a value for the desirable cumulative chloride balance has been established does not mean that it should not be constantly reviewed. The main reason for review is to check on errors that might be made in determining the chloride balance and to detect abnormal accumulations of fluid. For example, suppose that peritonitis develops in a patient with a desirable cumulative chloride balance of plus 400 milliequivalents and that fluid accumulates in his peritoneal cavity. This fluid is unavailable to the body and must be replaced just as though it had been lost from the bowel. Yet this loss does not show on the balance sheet. The net result is that the estimate of the patient's desirable cumulative chloride balance will have to be increased by several hundred units, say, to plus 700 milliequivalents. The exact figure will have to be determined.

The above discussion serves to emphasize again a basic point in parenteral fluid therapy, namely, that laboratory tests are no substitute for clinical judgment. Water-chloride balance data refine and improve clinical judgment; they do not replace it.

TYPES OF CASES IN WHICH WATER-CHLORIDE BALANCE STUDIES HAVE PROVED OF PARTICULAR VALUE

A man aged 83 had postoperative gastric retention. In spite of seemingly large amounts of salt and water given parenterally, he became salt depleted and alkalotic. Water-chloride balance studies were started; these indicated that the patient should receive 8 liters of fluid and 600 milliequivalents of chloride in a 24-hour period. In spite of a lowered cardiac reserve, this amount was given slowly and carefully. The patient benefited greatly and did not show evidence of congestive heart failure. After three more days of treatment, his gastric retention was relieved and he recovered.

Giving a man 83 years of age 8 liters of fluid in one day would have seemed rather drastic had it not been for the water-chloride balance studies, which clearly indicated the need for this vigorous treatment.

A boy 8 months of age underwent ureterosigmoidostomy for exstrophy of the bladder. Thirty-six hours after operation he had generalized convulsions without apparent cause, and his condition became critical. Water-chloride balance data, which had not been available to the physician in charge, revealed that although the volume of urine had been satisfactory it had not been large enough to keep up with the rate of infusion of dextrose solution being given to maintain an adequate urinary volume. The data showed a retention of water without a retention of salt; in other words, overhydration from excess of water was causing water intoxication. Two per cent sodium chloride in 10 per cent solution of dextrose stopped the convulsions almost immediately, and the patient recovered uneventfully.

Water-chloride balance studies may have been lifesaving in this case, because the diagnosis of water intoxication would have been difficult to make without them, as evidenced by the fact that it was not made until they were available. Similarly water-chloride balance studies by demonstrating early a retention of water in the presence of oliguria have facilitated the early diagnosis of impending primary renal shutdown; such studies also facilitate better management of this difficult problem.

A boy aged 8 years had aspiration pneumonia after an emergency operation for obstruction of the bowel. Four days after operation the physician in charge consulted the fluid balance service because of a plasma bicarbonate level of 41 milliequivalents per liter, which was believed related to the continued aspiration of gastric juice. Water-chloride balance data revealed that the gastric aspirate had been neutral instead of acid and therefore could not explain the "alkalosis." The data also revealed that the high bicarbonate level with hypochloremia was due to renal excretion of an acid urine high in chloride.

[24] Randall, H. T.; Habif, D. V., and Lockwood, J. S.: Sodium Deficiency in Surgical Patients and the Failure of Urine Chloride as a Guide to Parenteral Therapy, Surgery 28: 182-207 (Aug.) 1950.

When these observations were correlated with the pneumonia, the correct diagnosis of respiratory acidosis was established. It was confirmed by a plasma p_H determination of 7.2.

This diagnosis was of more than academic interest because it prevented the giving of ammonium chloride to lower the serum bicarbonate level, which would have made the acidosis worse.

SUMMARY

The importance of maintaining normal water and electrolyte balance and the inadequacy of present methods of accomplishing this in difficult conditions suggest a need for more exact methods of planning treatment for patients with complicated problems of fluid balance.

The goal of parenteral salt and water therapy is the maintenance of total body salt and water at a desirable level. Since water-chloride balance studies accurately measure changes in this level, they provide a reasonable basis on which to plan treatment. The clinical determination of water-chloride balance may now be accomplished with acceptable accuracy and at low cost by a new technic for the accurate bedside determination of chloride. Such water-chloride balance studies have been found of value in planning water and electrolyte dosage for several reasons:

1. They inexpensively provide a factual basis on which to plan treatment based on the individual need rather than on tests, rules or formulas. At the same time, they provide early warning of errors in treatment. Better care is therefore given at lower cost.

2. Water-chloride balance studies encourage physicians to think in terms of the total amount of sodium and chloride in the body as well as in terms of the concentration of these substances in the plasma.

3. Water-chloride balance studies make the management of problems of fluid balance more interesting and instructive and provide an excellent basis for teaching the principles of water and electrolyte metabolism.

4. Because nurses soon realize that the patient's welfare often depends on the reliability of their charting, the nursing staff is stimulated to be more accurate and precise in their recording of data on intake and output. The reliability and therefore the usefulness of these data are thereby increased.

ABSTRACT OF DISCUSSION

Dr. Victor Richards, San Francisco: Some eight years ago Dr. Scribner and I first became interested in this problem of fluid balance. At that time, the only methods available for deciding on requisite fluid and electrolytes for patients were chemical analyses of the blood. The ions most commonly considered are the sodium, potassium, chloride and bicarbonate. It is extremely difficult—and impossible in the ordinary hospital—to get any of these studies done. Hence, this approach to determination of requisite fluid and electrolytes on the basis of the cumulative chloride balance is of tremendous value. The only possible source of error is in those conditions in which sodium and chloride are excreted independently. However, I do not believe this objection obtains if one will follow these patients daily and make the cumulative type of study which Dr. Scribner has described. Similarly, one need not be concerned about discrepancies of sodium and chloride if the p_H of the material which is excreted is followed. That will enable the physician to decide whether the person has become acidotic or alkalotic, and that in turn will enable him to predict body sodiums accurately on the basis of chloride determinations. This is an extremely simple and effective measure for deciding the body needs of water, sodium and chloride. Dr. Scribner has not commented about potassium, and that is one source of difficulty which might arise in predicting body fluids and salts solely on the basis of the chloride technic. About 50 milliequivalents of potassium is lost daily, and in these patients this method of calculation is perfectly satisfactory if the potassium loss is added in addition with about 50 milliequivalents a day, plus the amount that is lost in these body electrolytes. This, then, is an extremely simple and inexpensive and practical way of settling the fluid and electrolyte needs of patients on an accurate basis without the necessity of detailed analysis of sodium, chloride and bicarbonate in the blood. It will be a great help in the handling of surgical problems of fluid and water balance.

Dr. Dwight L. Wilbur, San Francisco: Drs. Scribner, Power and Rynearson are to be congratulated on bringing to the bedside a simple, effective way of determining the needs for water and chlorides of the patient who, postoperatively or because of cardiac or renal disease, is apt to develop deficiencies in his electrolyte and fluid balance. It is surprising that so many patients have done so well after the parenteral administration of fluids. The amount and the chemical content of fluids so administered often have been determined largely by guessing the needs of the patient. Frequently a patient has been in serious imbalance which has not become apparent until the occurrence of edema, cardiac or renal embarrassment, or death. By the authors' methods fairly accurate information can be obtained concerning the chloride and fluid balance of the patient, and therefore his daily needs may be estimated. Most important, however, imbalance can be detected and corrected before serious complications occur. This method is not only clinically effective but useful in training the physician and surgeon at the bedside to think in terms of the total metabolism of salt and water and not merely in terms of the concentration of chloride in the plasma or the amount of urine excreted. Finally, this simple method has the merit of prevention at small cost of the complications and diseases that are costly both economically and in terms of morbidity and mortality.

Dr. Belding H. Scribner, Rochester, Minn.: We have attempted to demonstrate that the determination of chloride balance is now available to everyone and can be accomplished inexpensively and without special facilities. We do not imply that because the data are readily available they are easy to interpret when first encountered. However, most of the trouble in learning to use these balance data is due to lack of familiarity with the concepts involved. For example, physicians are accustomed to thinking of a patient's sodium chloride requirements in terms of the concentration of electrolytes in the serum. Balance data require that these requirements be thought of in terms of the total amount of sodium chloride in the body. It is desirable that this be done, and with a little practice one can soon learn to use water-chloride balance data effectively to determine the daily salt and water requirements of patients. These water-chloride balance studies make the management of problems of fluid balance more interesting and instructive because they tend to explain some of the basic principles of fluid balance in terms of the patient who is being treated. If a physician is interested in learning about renal regulation of acid-base balance, our technics enable him to observe the regulation as it operates in his patients. Suppose a balance study is being conducted on a patient in whom gastric retention develops and who requires gastric aspiration. First, the balance sheet will indicate whether the gastric aspirate is extremely acid, suggesting that more chloride than sodium is being lost and that an alkalosis may develop. If the alkalosis does develop the physician can observe a negative chloride balance, a lowering of the output of chloride in the urine and, most important, a pronounced shift in the urinary p_H to the alkaline side, indicating that the kidney is attempting to correct the situation by excreting a urine which is high in sodium and low in chloride. By being able to follow such events in his own patients a physician will soon discover that these water-chloride balance studies continually dramatize the principles of fluid balance and thereby encourage him to learn more about them.

ACCIDENTS, CHILDHOOD'S GREATEST PHYSICAL THREAT, ARE PREVENTABLE

HARRY F. DIETRICH, M D
Beverly Hills, Calif.

After 1900, patient, painstaking and often brilliant work in the fields of public health and preventive medicine resulted in dramatic reductions in the morbidity and mortality of most infectious diseases; since 1936 the success of antibiotic therapy and chemotherapy in the most fearsome infections has resulted in even more miraculous reductions in mortality rates. Yet the very triumph of modern antibiotic and chemotherapeutic medicine has given new statistical significance to an old problem. Over 100 years ago Condie[1] wrote, "Burns and scalds are among the most frequent accidents that occur. . . . The carelessness of parents and servants, the natural temerity and incautiousness of children . . . render these accidents of such frequent occurrence. . . ." The recent precipitous decline in death rates from disease is in shocking contrast to the essentially unchanged death rate from accidents.

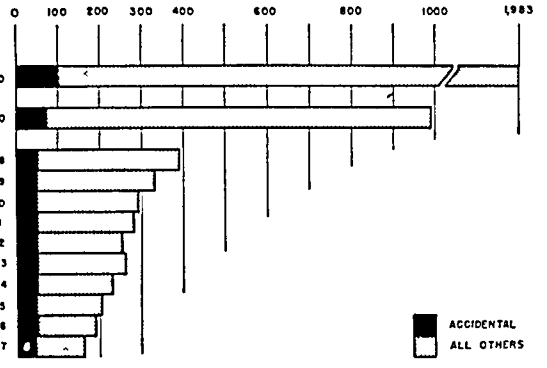

Fig 1 —Chart showing the decrease in total death rates due to public health and preventive medicine and modern therapy The rate constancy and growing importance of accidental death is apparent (The accident rate of 1900 was unobtainable.)

Figure 1 tabulates the diminishing death rates from disease and the too constant death rate for accidents in preschool children of one to four years of age.

Accidents now kill more children than any single disease and actually account for one third as many deaths as all diseases combined. In figure 2 the number of deaths from accidents is oriented in the five commonest causes of death for the one to four year age group.[2] That two different groups of accidents rank in the first five causes of death is worthy of serious thought and positive action. Figure 3 requires no comment; it illustrates the relative frequency of accidental death compared to the next commonest cause or causes of death for the indicated age groups. It forces the question, however, "Do we expend our money, efforts and emotions combating the most important threats to our children, or is most of our concern with dangers of secondary importance?" Though not to be belittled, the problems of poliomyelitis, heart disease, cancer and tuberculosis in children are dwarfed by the physical and emotional devastation brought by juvenile accidents. The leading lethal role of accidents has somehow escaped proper emphasis, but it cannot be challenged; over a year ago the magnitude of the problem was aptly indicated in The Journal of the American Medical Association.[3]

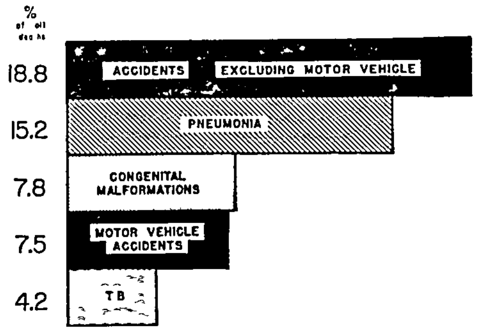

Fig 2.—Leading causes of death of children aged one to four years in the United States in 1947. In this age group accidents not only rank as the leading cause of death but occupy two of the first five positions as causes of death

In one year over 12,500 children were killed by accidents.[4] How many children were permanently crippled is completely unknown. Roberts and Gordon,[5] in studying home accidents (all ages) in Massachusetts, found that for every person killed 150 were injured and four received permanent disability. Temporary application of this estimate (for lack of another figure) to the juvenile accident field would suggest that approximately 50,000 children a year were permanently injured in the United States.

This tremendous morbidity and mortality has excited only desultory thought and uncoordinated action by the medical profession. Wheatley[6] has indicated that the United States Children's Bureau, the National Safety Council, the Academy of Pediatrics and the Metropolitan Life Insurance Company are aware of the problem; the last named has perhaps been most active in its attack. In industry, aviation and traffice management much has been written about accidents and their

economic significance; few investigators have attempted to establish basic concepts in the field of accident prevention. Roberts and Gordon have intimated that there is an epidemiology of accidents. Over 10 years ago Godfrey[7] urged that accident prevention be considered a public health problem and stressed the importance of home accidents. Armstrong and Cole[8] have been particularly interested in studying home accidents among certain insured groups. Manning[9] briefly mentioned accident prevention in her prize-winning essay on preventive medicine. The Bakwins[10] reviewed the psychological implications in the accident-prone person, and Ackerman and Chidester[11] analyzed an aggravated case in a child. In England special commissions have been activated to survey the problem, and in one town studied 9 per cent of the children under 10 years of age received hospital treatment for accidents during one year.[12] A few specialists have become concerned with the accidental tragedies in their patients. Jeancon[13] is mentioned because that concern has expanded her activity from ophthalmology to the general field of accident prevention in children. Graves[14] summarized the importance of accidents in children and pointed out the household areas where particular care should be exercised. Separately he emphasized the need for accident prevention in pediatric nursing.[15] Recently Esther Clark[16] dramatically pointed out the importance of accidents as a cause of childhood death and emphasized the "life years" and "working years" lost by juvenile accidental death. Spock indirectly indicated the close relation between accident prevention and general child-parent relations.[17] Each author writes of protecting the child from poisons, pots and pools, but no one has formulated a general theory of accident prevention in childhood.

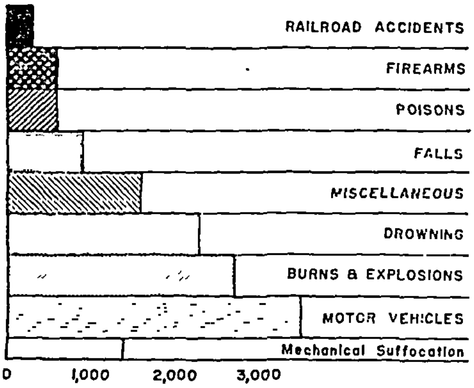

Fig. 4.—Chart showing the number of deaths from the various types of common accidents in the United States in 1947 involving children (14,000) under 15 years of age.

Here is a problem to challenge every member of the medical profession, and it must do so individually. The problem of accident prevention in childhood is unique. No endowed foundation, no research laboratory and no inspired investigator is going to develop a vaccine, serum, antibiotic, endocrine extract or operation that will prevent accidents. Though interest, thought and statistical research can be stimulated at the community level, the ultimate mediators of any accident prevention program in childhood are the parents. They must be reached individually or in community groups by the physician, who must offer a reasonable theoretical solution. Even though a physician may not choose to work on the problem at the community level, he cannot escape his responsibility of functioning effectively in the doctor-patient relation. No specialty can validly disclaim this responsibility.

In the discussion to follow it must be emphasized that "accidents" refers only to lethal, or physically, psychologically or economically crippling types of injury. Burning, drowning, poisoning, crushing, shooting and mangling include most of the serious accidents. Bowden[18] has most recently shown that "smothering" belongs in the same diagnostic wastebasket as "thymic death"; it should, in all but the rarest of instances, be deleted from the figures on accidental deaths. The earlier mention of "over 12,500 annual accidental deaths" has already been reduced by 1,400 alleged instances of suffocation. The relative frequency of the various fatal accidents is shown in figure 4.

Just as the normal child will suffer certain not overwhelming frustrations without permanent emotional disfigurement, so in the process of ambulation, exploration and education must he expect certain minor injuries. Split lips, polychrome lumps, chipped deciduous teeth, blistered fingers, simple fractures and gory but not gruesome lacerations must be accepted as normal wear and tear; properly handled by the physician and the parents, they can be of positive educational value.

THEORY OF ACCIDENTAL PREVENTION

How can the physician advise on accident prevention? In adults accident prevention must be engrafted like ritualist manners or military courtesy; more rarely it can be taught as an intellectual discipline. A theory of accident prevention which embraces a changing reciprocal relation between protection and education seems needed in work with children; the relative roles of these two components related to age is suggested in figure 5. Briefly stated, pediatric accident prevention begins with 100 per cent protection at birth; this protection must be absolute and must be maintained through most of the first year of life. The nonambulatory infant under one year of age, who is not adroit at dodging, is completely at the mercy of its custodians. If he is burned, crushed, drowned, poisoned or mechanically mangled it is directly the fault of the persons responsible for his care; the

responsibility of the physician to instruct parents is obvious. Accident prevention in the young infant is therefore remarkably simple. However, if such absolute protection were maintained for a relatively few years the child would be unusually vulnerable to accident.

As indicated in the graphic representation of the theory of accident prevention in children, the early introduction of a rapidly increasing component of education is essential. While maintaining protection against serious accidents, parents should expose children who have reached the age of one year to the educational value of minor painful experiences. This is the beginning of an important and difficult period, for by 6 or 7 years of age the child should need protection only from previously unexperienced or incomprehensible perils. He will still need frequent reminders, but protection in general is infeasible because his activities move him physically from the sphere of parental influence. Education accompanies the child; protection remains at home. It is obvious then that the 1 to 5 year age period is the critical one. Here the pattern for future safe conduct (as most other behavior patterns) is set.

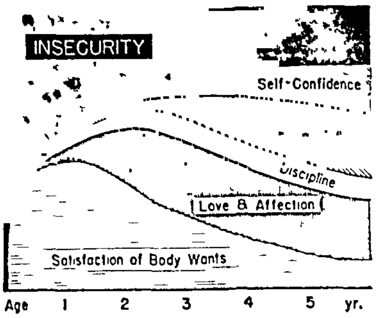

Fig. 6.—Illustration of the development of "sense of security," with the relative importance of the several components related to age.

It is impossible didactically to present rules for each child at each age. The interests, imagination and opportunities of the individual youngster are too varied. However, certain major catastrophies threaten every child. One may consider as examples some of the main threats to a 20 month old infant and how the parents might combine protection and prophylactic education. In the prevention of serious burns the parents should never allow the infant to be near the stove (in use or not), an open flame or potential electrical hazards. Even casual handling of matches or lighters should not be permitted, for the infant cannot appreciate their inflammable potentialities. This is protection. The heat of any commonly hot article, like a coffee pot, should be repeatedly demonstrated by lightly touching the child's hands to it. With proper warnings, the contacting of a lighted cigaret should be encouraged to clarify and emphasize the "hot" concept. This is education. With the child's climbing abilities well in mind, the parents should place poisons and caustics out of reach; a bottle of vinegar or a jar of hot mustard left where discovery is inevitable may well provide the first lesson that not everything in bottles is pleasantly imbibable. No young infant should be allowed near machinery with exposed moving parts (wringers, sewing machines, farm implements, lawn mowers, electric fans), but a finger nail torn or bloodied in the exploration of a manual egg beater is a small price to pay for initiation of respect for the moving parts of machinery.

The first educational step in the prevention of drowning presents a peculiarly difficult problem. For over a year and a half parents have, by every action, indicated to the infant only the virtues of water. They have encouraged his drinking of it, they have made a fetish of using it on his face, hands and body, they have laughingly and rightly encouraged his playing with it and have highly praised him when he has deposited his precious excreta in it. Now they are faced with the apparent paradox of convincing him that it, in large amounts, is dangerous and bad. The aim should be to teach him respect for, rather than fear of, deep water. If, instead of spending the daily bath time fallaciously proving to the infant that he is unsinkable ("look at baby swim"), they occasionally let him discover that he cannot stay afloat and that water in the air passages is not comfortable, they could, without instilling fear, encourage respect for deep water.

It must be obvious that for any one child the prevention of a particular type of accident will employ varying protective and educational pressures at different ages. The presentation here of the problem of serious falls in the male is not all-inclusive. During the first year of life the prevention is protection—the infant should neither be dropped nor allowed to drop. Protection must be 100 per cent. As soon as the infant becomes ambulant the problem is more complicated. He must be protected against serious falls and at the same time must gain a respect for the potentiality of falling. He must not be allowed to fall from dangerous heights, nor on dangerous surfaces, nor with dangerous objects in his hands. Thus upstairs screens must be nailed; pools, ditches and ponds must be fenced or effectively prohibited, and cellar doors must be locked. The child should be permitted to fall out of chairs (education) but not with potentially dangerous implements in his hands (protection). He must gradually be taught in minor, painful (but not lethal or crippling) ways the concept of gravity and falling. When the child begins to climb, his actions should be neither forbidden nor dramatized. He must be taught to expect falls and therefore to think about where he is going to fall. Minor falls should not be poulticed with major emotional or gustatory awards. He should be instructed to keep the area where he might land in a fall clear of garden tools, wagons and other secondarily injurious objects. He should be taught that climbing is a skill to be practiced, not an accomplishment to be socially exploited. The interested boy eagerly accepts instruction in how to test footholds—on branches, fences and rocks. He gladly learns how to pick the safest landing areas and body attitudes in case a fall is unavoidable. The natural mechanistic interests of the 7 to 9 year old boy lend themselves to an appreciative acceptance of the care, use and dangers of ropes, pulleys and ladders. Finally, after many intermediary experiences, the young man arrives at the age of 21 years. Whether he is climbing power poles for a living or clambering up mountains for fun, he will unconsciously employ an accumulated body of knowledge and skill for accident prevention; but in dangerous situations he still will avail himself of the protection (enforced by company order or elected by himself) of a safety belt or pitons and a rope.

I have suggested that the reciprocal relation of protection and education related to a child's age constitute a workable theory of accident prevention. This implies that the theory is applicable by the parents. It is. The tools needed are forethought, time and discipline. The forethought must be devoted to anticipation of the child's interests and activities. "He hasn't turned over yet" is an attitudinal invitation to disaster. "Your garden job this week" is avidly read by many parents who still in practice apparently subscribe to the "a child is a child" philosophy; they fail to anticipate constantly changing interests and activities. Here the physician can supply valuable advice and can probably aid by suggesting graded educational situations. Time might seem to be a limiting factor, but if physicians would allay parental worry about nonessential and nonremediable worries, mothers and fathers would have the time necessary to insure the safety of their children.

Without being facetious or flippant, I maintain that, if all the time wasted by parents on fruitless worrying about poliomyelitis, nineteenth century worrying about the size, shape and color of bowel movements, harmful worrying about appetites, puerile worrying about temporary cosmetic blemishes, guilty worrying about juvenile masturbation and competitive worrying about their children's ounces and inches—if all this wasted emotional effort and time were employed in thinking about accident prevention, parents would have more living children. Again the physician's role is clear and unavoidable. He must be careful lest he magnify, by his attitude, his treatment or his charges, the parents' worries about less important problems. Parents must be shown that pimples, poliomyelitis and pounds are relatively unimportant problems. They must be shown that accidents present a greater hazard than the threats our too thoroughly propagandized society ordinarily fears for its children. Accidents are brutal and basic. Then, too, parents must be convinced that the prevention of serious accidents is possible by their own efforts. But forethought and time are not enough.

The third indispensable tool for the application of the theory of accident prevention in children is discipline. Misinterpretation of modern psychological and psychoanalytical thought has robbed too many children of the emotional security and physical protection that is afforded by mild, consistent, understanding and logical discipline. There is perhaps no child so basically insecure as the youngster who knows that his parents will not control his accidental, experimental or vindictive threats. There is perhaps no young adult so emotionally vulnerable to the pressures of a frustrating civilization as the young adult who has not had to cope with some childhood frustrations. In general, mild discipline, introduced in the last few months of the first year, must be reinforced and expanded in scope during the second year to protect the child against all the major threats to his safety that cannot be removed from his reach. During the second year active discipline should probably have no other objective. To be safe, the 20 month old infant must be trained (disciplined) to stay away from the kitchen stove, all machinery, electrical outlets and connections, fire-making contrivances and the streets. Throughout childhood there must remain a leash (not lash) of discipline to serve where reason cannot—and from this leash will ultimately develop the halter of self discipline.

RELATION OF ACCIDENT PREVENTION TO EMOTIONAL SECURITY

If it had none but its obvious value—the prevention of death and crippling in children—accident prevention would be worthy of the attention of all physicians. However, accident prevention is not an isolated facet of child care. In its dynamic conception it is an integral part of the emotional development of children. It is beyond the province of this discussion to attempt to detail the development of a sense of security in childhood; for brevity's sake figure 6 is offered as a graphic representation of the relative importance of the various factors involved at different age levels. If the concept is accepted that the desire for "lack of pain" is one of the basic body wants, then the contribution of an accident prevention program to each of the components of a sense of security is obvious. A child's assurance of parental love and affection is immeasurably enhanced by his knowledge that his parents will not permit him to perform any truly injurious act. His need for discipline is fruitfully satisfied. His sense of physical security is augmented. An imaginative accident prevention program adds tremendous increments to both self confidence and knowledge. In brief, there is certainly no other phase of the parent-child relation which so broadly and literally enhances a child's sense of security.

THE PHYSICIAN'S ROLE

A medical problem of tremendous importance to the health and life of children has been defined. A practical theory for the prevention of accidents has been presented, and the tools necessary for the application of the theory have been enumerated. The responsibility for the distribution of this information to parents rests primarily on the medical profession. We physicians will be most remiss in our obligations to insure the health of children if we do not initiate and continually activate programs of accident prevention. Such activity by the medical profession should logically proceed at several levels:

1. The patients of individual physicians should be appraised of, and advised on, the problem of accident prevention in children. The frequency of accidental death and crippling should be placed in its proper perspective, which implies sound education of the laity on other medical problems. Press [19] suggested that, when, at the time for the child's immunization, a mother expresses the wish that she could "take the baby's shot for him," she should be reminded that only she can "immunize" him against the greater threat and pain of serious accident.

2. Community resources should be recruited to adopt accident prevention programs as primarily important ones. As was editorially stated in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION [20] ". . . as professional men and citizens they (physicians) are free to take the initiative. Individually, and in civic or municipally sponsored groups, members of the medical profession have a compelling responsibility. Physicians can play an effective, even dramatic, role in the prevention of accidents. . . ." Armstrong and Cole [21] have provided a workable outline for the organization of community accident prevention. These same resources should be informed of the truly vital importance of obtaining accurate figures on crippling due to accidents. The economic effects of childhood accidents provide another field for fruitful survey.

3. Additional attempts must be made to stimulate, at national levels, an active appreciation of the problem of accidental death and crippling in children and an awareness that the problem is not insoluble.

It should further be pointed out that parents who are thoughtful about the possibility of accidents to their children will unconsciously be thoughtful about themselves, whether they are in an oil refinery, a mine, a kitchen or an automobile or on a farm. This intensification of adult awareness of accident hazard through child safety programs should be worthy of nurturing

by the American Red Cross, the Blue Cross and similar hospital plans, the National Safety Council, all national industrial groups and insurance companies. The intimate relation between accident prevention programs in children and the development of a sense of security should be brought to the attention of the various mental hygiene movements, juvenile parole associations and similarly motivated national groups. In all of this the physician must be the activator. Here is an opportunity for the physician who has no research grant, no medical school teaching affiliation, no laboratory training and no investigative experience or opportunity to aid tremendously child health at the family, community or national level.

SUMMARY

Accidents constitute the greatest single threat to children's lives and physical health. How many children are permanently crippled by accidents is not, but should be, known. A theory of accident prevention embracing a changing reciprocal relation between protection and education is suggested. The practical application of such a theory requires forethought, time and discipline. A properly applied program of accident prevention contributes to each component of a child's sense of security. While the ultimate mediation of an accident prevention program in children rests with the parents, the immediate responsibility falls on, and must be accepted by, the medical profession.

Clinical Notes, Suggestions and New Instruments

AGRANULOCYTOSIS DUE TO GANTRISIN®

Report of a Case with Recovery

E. A. HAUNZ, M D.
J. D. CARDY, M D.
and
C. M. GRAHAM, M D
Grand Forks, N D

Gantrisin,® previously designated NU-445, is 3,4-dimethyl-5-sulfanilamide isoxazole. Since early in 1946 this sulfonamide has had rather extensive experimental and clinical trial,[1] and all observers repeatedly emphasized the apparent low toxicity of the drug. Though infrequent, the usual toxic phenomena incident to the use of other sulfonamide compounds have been noted, including dermatitis,[2] anorexia,[3] nausea, vomiting,[4] headache,[5] fever,[2a, h] vertigo,[2f, g] crystalluria[6] and hematuria[7] A review of all available published clinical reports to date discloses only eight instances of leukopenia[2f, g] Neutropenia of moderate degree was present in two of these eight cases. In neither of the two cases were neutrophils depressed below 30 per cent[8] However, in several clinical reports specific mention of leukocyte counts was not made.

The present case of true agranulocytosis due to gantrisin® is reported because: (1) to our knowledge this is the first instance of total disappearance of granulocytes following the use of this drug, and (2) it is hoped that this report will serve to discourage indiscriminate use of the drug.

REPORT OF CASE

History.—A woman aged 47 was examined by one of us (C. M. G.) on Jan 4, 1950. Her chief complaints were slight frontal headache, running nose, nonproductive cough, myalgia and general malaise of five days' duration. Inquiry into the past history was noncontributory except for a "cold" one month previously, for which the patient had not consulted a physician.

Physical Examination.—The patient was well nourished and did not appear acutely ill. The temperature was 102.4 F., the pulse rate 100 per minute and the respiratory rate 18 per minute The scleras, nasal mucosa and pharynx were moderately injected. The neck, heart, lungs, abdomen, pelvis, rectum, extremities and central nervous system were entirely normal.

Treatment.—The diagnosis at this time was acute upper respiratory infection. Therapy consisted of steam inhalations, bed rest and administration of aureomycin hydrochloride 250 mg. every six hours Within 12 hours the patient was afebrile and generally much improved. However, the symptoms recurred after 24 hours, the temperature rising to 102.5 F. Aureomycin therapy was stopped on account of nausea of the patient, who was then given 600,000 units of procaine penicillin G in peanut oil intramuscularly every 24 hours, together with 1 Gm. of gantrisin® every three hours. High fluid intake was encouraged. The only other medicaments prescribed were aspirin (acetylsalicylic acid) 10 grains (0 65 Gm) and codeine ½ grain (0.03 Gm) every four hours as necessary for headache and malaise On the fifth day of this regimen the temperature of the patient rose to 104 F. and she appeared acutely ill, now complaining of sore throat, burning distress in the substernal and epigastric regions, moderate prostration and severe pain in the head, neck, back and muscles.

[8] Thompson, H T.· Personal communication to the authors.

On Jan. 10, 1950 she was admitted to the Grand Forks Deaconess Hospital. The temperature was 104.6 F., the pulse rate 130 per minute and the respiratory rate 20 per minute. The scleras were not injected. A round, sharply circumscribed 0.5 cm. lesion with necrotic center and erythematous periphery was noted on the buccal mucosa opposite the right lower canine tooth. Likewise, two smaller lesions were noted on the lower anterior buccal mucosa. No other skin or mucous membrane lesions were in evidence. The nasal and pharyngeal mucosa appeared normal. The blood pressure was 140 systolic and 75 diastolic. The heart, lungs, pelvis, rectum and reflexes were entirely normal. There was moderate tenderness in the epigastrium, but no masses were palpable. The spleen definitely could not be palpated.

Roentgen appearance of the chest was normal except for a calcified primary tuberculous complex in the left hilar region and moderate increase in bronchovascular markings throughout both lung fields. The urine was normal except for a trace of albumin. The hemogram showed red blood cells 3,990,000 per cubic millimeter and hemoglobin 12.2 Gm. (72 per cent). White blood cells were counted three times and averaged 1,500 per cubic millimeter. The differential count showed total absence of granulocytes, 78 per cent lymphocytes, 22 per cent monocytes, no eosinophils and no basophils. Bleeding and coagulation times were normal. The blood platelets numbered 282,000 per cubic millimeter. Subsequent differential counts were made on buffy coat smears, and these results together with serial white blood counts are shown in the accompanying table. Agglutination tests for infectious mononucleosis, typhoid, paratyphoid and brucellosis were negative.

Course in the Hospital.—The patient became progressively worse for four days after admission to the hospital. She complained of extreme weakness, burning substernal and epigastric distress, sore mouth, headache and chilly sensations. Fever was intermittent, rising to 103 F. or less several times daily. The first few days of therapy consisted of strict bed rest, orally given aureomycin 500 mg. every six hours, aqueous crystalline penicillin G 100,000 units intramuscularly every three hours and pentnucleotide® (an 8 per cent solution of the sodium salts of four pentose nucleotides derived from yeast nucleic acid by mild alkaline hydrolysis) 2 ampules daily intramuscularly. Gantrisin® therapy was discontinued immediately on discovery of leukopenia and agranulocytosis. In addition to these measures the patient received 250 cc. of whole blood twice daily from January 12 to 14 inclusive. On Jan. 11, 1950 new lesions, similar to those described previously, were noted on the epiglottis.

Blood Picture in a Case of True Agranulocytosis Due to Gantrisin®

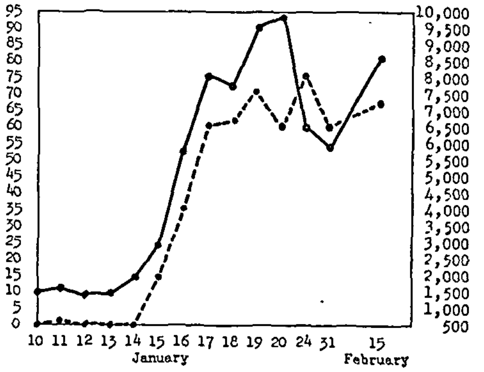
The accompanying chart depicts the rise in total leukocytes with the reappearance and precipitous rise of neutrophils. Total absence of granulocytes persisted for five days after the diagnosis was made. A dramatic rise from zero to 60 per cent occurred in only three days, and similarly total leukocytes rose from 1,950 to 8,000 during the same period. Improvement in the patient's symptoms paralleled reversion of the blood picture to normal. Several peripheral blood smears were made daily from January 10 to 20 inclusive and appeared essentially normal except for the disturbance in granulocytes and total leukocytes (table). No buffy coat was demonstrated in the centrifuged venous blood specimens from which peripheral smears were made from the top millimeter of the packed cells.

Bone marrow aspirations were performed on Jan. 12 and 15, 1950. Each specimen was aspirated from the sternum, treated with heparin-oxalate mixture and centrifuged; smears were made from the buffy coat. Examination of smears taken on January 12 showed the nucleated red cell elements to be relatively increased. Maturation was of the normoblastic type, but there appeared to be an arrest in development at the level of the late polychromatophilic stage. The earlier developmental stages were well represented, but few late polychromatophilic forms were present. They comprised only 6 per cent of the 32.5 per cent red cell elements. No orthochromatic normoblasts were found. Megakaryocytes were few but probably not reduced below the normal number. Their morphology and that of the platelets appeared normal. The differential count of nucleated cells was: "blast" forms 9 per cent; promyelocytes 15 per cent; myelocytes 5 per cent; metamyelocytes (all types) zero; red blood cells 32.5 per cent; lymphocytes and monocytes 38.25 per cent; neutrophils zero; eosinophils zero, and basophils 0.25 per cent.



Graphic presentation of the reappearance of neutrophils and rise of total leukocytes in peripheral blood in a case of true agranulocytosis due to gantrisin.® The figures at the left represent the percentage of neutrophils (broken line on chart), the figures at the right the leukocytes per cubic millimeter (solid line on chart).

The absence of the late developmental forms of granulocytes was striking. There was a relative increase in myeloblasts, but probably no actual increase in their number. These cells showed normal structure. In some instances the promyelocytes showed heavy, coarse, azurophilic granulation. Myelocytes were reduced in number, both relatively and absolutely. Many of those seen had large vacuoles and multilobed nuclei. This was believed to be an artefact due to the use of oxalate. (However, at the time of the second marrow aspiration on Jan. 15, 1950 a direct smear was made before contact with oxalate. In this preparation vacuoles were also noted in the myelocytes, but the change was not nearly as pronounced as in the portion of the specimen treated with the heparin-oxalate mixture.)

No metamyelocytes of any type were seen, and, with the exception of two damaged basophils, no mature granulocytes could be found. All granulocytic forms from the late myelocyte on had completely disappeared. The lymphocytes and monocytes were relatively increased in the marrow. The lymphocytes showed functional changes similar to those seen in the peripheral blood. No abnormal cell forms were noted. These smears were also reviewed by Dr. M. M. Hargraves of the Mayo Clinic, who concurred in the opinion that they were typical of agranulocytosis secondary to drug sensitivity.

Examination of peripheral blood smears on Jan. 12, 1950 showed slight anisocytosis and hypochromia of red blood cells. There was no evidence of red cell regeneration. Platelets appeared to be present in normal numbers and to have typical morphologic characteristics. Leukocytes were greatly reduced in number. The white blood cell count was 1,400. The differential count (see table) was lymphocytes 77 per cent and monocytes 23 per cent. No neutrophils could be found in several smears. A sample of venous blood was drawn, using a commercial heparin-oxalate mixture as anti-coagulant, and centrifuged. No buffy coat was apparent. Smears made from the top millimeter of the packed cells showed essentially the same differential count, and neutrophils were not seen. Eosinophils and basophils were absent. The lymphocytes showed mild functional alterations. The monocytes showed no apparent morphological change.

A second sternal aspiration on Jan. 15, 1950 showed the following differential count of nucleated elements: "blast" forms 3 per cent; promyelocytes and myelocytes 34 per cent; metamyelocytes 19 per cent; red blood cells 22 per cent; lymphocytes 21 per cent; neutrophils 1 per cent, no eosinophils and no basophils. Comparison with previous smears showed a decided increase in the number of orthochromatic normoblasts. The granulocytic series showed pronounced change. Myelocytes had greatly increased in number, and metamyelocytes had reappeared. As previously mentioned, myelocytes and metamyelocytes showed small vacuoles in the direct smear. Vacuolization and bizarre multilobed nuclei were frequent in smears made from the buffy coat after the use of an anticoagulant mixture.

The patient made a complete recovery and was discharged from the hospital on Jan. 20, 1950. Subsequent leukocyte and differential counts on peripheral blood were normal. She was last seen on Aug. 10, 1950, when complete physical examination and blood studies indicated that her general health was excellent.

COMMENT

Although it cannot be proved with certainty that gantrisin® caused the agranulocytosis in this case, we believe it is fair to assume that the drug was the most likely cause. None of the other medicaments given prior to the onset of the patient's agranulocytosis are known incitants of this phenomenon. In any event it is highly improbable that penicillin or aureomycin could be responsible, because these drugs were administered during the course of the agranulocytosis from which the patient recovered. Furthermore, it was estimated that the patient took a total of 30.0 Gm. of gantrisin® over a period of five days, an amount which is more than adequate to depress the granulocytes should sensitivity to the drug occur.

SUMMARY AND CONCLUSIONS

A case of true agranulocytosis probably resulting from the use of gantrisin® (3,4-dimethyl-5-sulfanilamide isoxazole) is reported. The onset and subsidence of the condition closely paralleled administration and discontinuance of the drug. Careful studies of peripheral blood and bone marrow and follow-up examinations of the patient served to exclude other blood dyscrasias.

This report is made with the hope of discouraging indiscriminate use of the drug. Even when used with the proper indications the leukopoietic status of the patient should be checked more consistently than appears to be the practice from a perusal of current literature.

221 South Fourth Street.

Blood Sugar and the Liver.—Soskin called the liver the primitive regulator of the blood sugar, which can operate in the complete absence of insulin and the pituitary. The stimulus which elicits the hepatic response is the blood sugar itself—the so-called "homeostatic mechanism." There is evidence that the liver is able to convert a wide variety of substances into glucose and glycogen, including carbohydrates such as fructose and galactose, proteins and fat. Hepatic gluconeogenesis is increased by the anterior pituitary hormone and inhibited by insulin. Epinephrine causes hyperglycemia, resulting in a sharp decrease, then rise of liver glycogen. In advanced hepatic disease hypoglycemia results. That the liver can convert lactic acid to glycogen and the muscle glucose to lactic acid is the basis for the Cori cycle. The removal of lactic acid by the liver is important in carbohydrate metabolism. By this cycle the muscle and liver glycogen become virtually interchangeable, which is clearly demonstrated by the action of epinephrine and in muscular action.—Jean T. Hugill, M.D., Liver Function and Anesthesia, *Anesthesiology,* September 1950.

Council on Physical Medicine and Rehabilitation

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

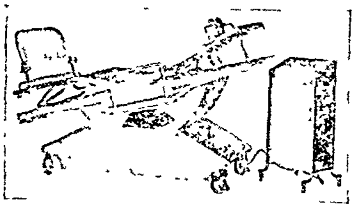
Howard A. Carter, *Secretary.*

McKESSON RESPIRAID ROCKING BED ACCEPTED

Manufacturer: McKesson Appliance Company, 2228 Ashland Avenue, Toledo 10, Ohio.

The McKesson Respiraid Rocking Bed is designed to aid respiration in certain diseases of the nervous system, particularly poliomyelitis, and to aid the circulation in cases of peripheral vascular disease. The apparatus is a bed with the spring and mattress so mounted that they can oscillate. The moving parts are provided with rests for the feet and shoulders to keep the patient from sliding back and forth on the mattress.

The unpacked apparatus is stated to measure 127 (height) by 101 by 198 cm. (50 by 40 by 78 inches) and to weigh 250 Kg. (550 pounds). Crated for foreign or domestic shipment, it makes three boxes weighing altogether 455 Kg. (1,000 pounds). It requires a source of 60 cycle alternating current at 110 volts and draws a maximum of 2,400 watts (20 amperes). The frequency of oscillation can be adjusted to from 0 to 30 times per minute.



McKesson Respiraid Rocking Bed

Evidence obtained from several acceptable sources led the Council to conclude that the rocking bed is useful but that hospitals should not be encouraged to purchase the apparatus with the idea that it is suitable for use in every type of emergency calling for artificial respiration. There was general agreement as to the value and limitations of this device. It does not take the place of the tank respirator but can be used as a means of weaning patients away from the tank respirator. The Council on Physical Medicine and Rehabilitation voted to include the McKesson Respiraid Rocking Bed in its list of accepted devices with the understanding that the manufacturer will not represent it as complete equipment for handling all types of respiratory failures.

SILVERTONE HEARING AID, MODEL M-35, ACCEPTED

Manufacturer: Micronic Company, 727 Atlantic Avenue, Boston 11.

Distributor: Sears, Roebuck & Company, 925 South Homan Avenue, Chicago 7.

The Silvertone Hearing Aid, Model M-35, is an electric device differing from the Micronic Model 101 (Council-accepted) only in the exterior etching and front grille design. Excluding the clothing clips and the projecting controls, it measures 105 by 58 by 22 mm. With batteries, receiver cord and receiver, it weighs 186.5 Gm. Evidence from sources acceptable to the Council showed that this device was satisfactory in construction and performance. The Council on Physical Medicine and Rehabilitation voted to include the Silvertone Hearing Aid, Model M-35, in its list of accepted devices.

IONIZING RADIATION AND BLOOD-FORMING TISSUES

Since Heineke's pioneering research 35 years ago, it has been known that the blood-forming tissues are extremely sensitive to ionizing radiations.[1] Studies on normal laboratory animals exposed to a single dose of whole body irradiation in the LD_{50} range (dose required to kill one-half the animals exposed within a period of 28 days after irradiation) have shown that the bone marrow and the lymphatic structures go through the following phases: (1) destruction characterized by disintegration of cells, (2) active phagocytosis of the cellular debris, (3) atrophy, during which free cells are absent or at a minimum, and, finally, (4) regeneration. In rabbits exposed to a single dose of 800 r total body irradiation, phases 1 and 2 usually are completed within 24 hours, phase 3 (atrophy) may persist to or beyond the tenth postirradiation day but phase 4 (regeneration), though sometimes beginning as early as the eighth or tenth day, may not be complete for three weeks or even longer.[2] In the bone marrow, complete recovery usually is prompt. Erythrocyte, thrombocyte and granulocyte precursors in the marrow may reach or exceed normal by the fourteenth postirradiation day, and in the peripheral blood this repair is reflected by a normal or even an increased number of reticulocytes, thrombocytes and heterophils (neutrophils in man). In the lymphoid tissue, however, though there is some diffuse regeneration in the first two weeks following irradiation, complete recovery is slow, lymphatic nodules in the lymph nodes and white pulp of the spleen being not yet normal by the fourteenth day and the number of lymphocytes in the circulating blood remaining below normal for 30 days or more. It has been assumed that free cells are restored to the atrophic hematopoietic tissue by regeneration homoplastically from a few scattered surviving free cells and heteroplastically from fixed cells, such as those of the reticulum, and that it is suppression of these restorative processes that accounts for delay in regeneration of marrow and lymphatic tissue. Some investigators believe that delayed repair is caused by direct irradiation damage to reticular cells or surviving free cells, while others maintain that the delay is caused indirectly by the general toxicity or specific toxicity of radiation injury to the body as a whole.

Jacobson and his associates have reported that, in mice exposed to total body irradiation of 1,025 r, mortality is strikingly reduced and regeneration of the hematopoietic tissue is complete within eight days if the spleen has been surgically exteriorized and shielded from irradiation with lead. Without such shielding, this dose kills all the animals within 13 days and their hematopoietic tissues show little or no regeneration. In rats the shielding of the spleen or in rabbits of the spleen or the appendix reduces to one week or less the time required for regeneration of marrow and lymphatic tissue following exposure to 800 or 1,000 r of irradiation. Several explanations are offered: 1. The sparing of this amount of lymphatic tissue may reduce the general "radiation toxicity." 2. The lymphatic tissue that remains intact by virtue of shielding may supply humoral stimulation to hematopoietic tissue that is damaged by irradiation. 3. Cells from the intact lymphatic tissue may seed or colonize the damaged hematopoietic tissue. 4. Irradiation of the spleen and appendix may produce agents capable of suppressing regeneration of hematopoietic tissue, and the avoidance of irradiation of these organs prevents the production of such agents.

Radiologists long have known that subtotal body irradiation produces a briefer and less profound hematologic suppression than does total exposure of the body. They have noted, also, that the suppression is greater for some body parts than for others and that irradiation of the spleen alone in cases of myelogenous leukemia may be followed by sharp reduction of circulating leukocytes and the disappearance of cutaneous lesions. There have been numerous attempts to demonstrate in nonirradiated tissues of experimental animals inhibition or destruction produced indirectly by irradiation of other parts of the body, but the results have been negative or, at most, equivocal. Jacobson and his group [3] appear to be the first to have investigated the reverse situation, namely, the effect of nonirradiation of certain tissues, such as the spleen, on heavily irradiated tissues elsewhere in the body.

Jacobson, L. O.; Simmons, E. L.; Marks, E. K.; Robson, M. J.; Bethard, W. F., and Gaston, E. O.: The Role of the Spleen in Radiation Injury and Recovery, J. Lab. & Clin. Med. **35:** 746, 1950.

The fact that the sparing of the spleen (which weighs only 1/2000 as much as the entire body of the rabbit) enables the heavily irradiated lymphatic tissue of the animal to be well on the way to recovery within four days indicates that the responsible factor or factors are potent and prompt acting and suggests that the agent may be a humoral factor supplied by the intact splenic tissue. If this proves to be the case, then perhaps the agent can be isolated, identified and eventually made available for the treatment of excessive exposure to ionizing radiation.

ACCIDENT PREVENTION IN CHILDHOOD

Dr. Dietrich, in a contribution to this issue of THE JOURNAL (page 1175), calls attention to the brilliant accomplishments in the last half-century in the fields of public health and preventive medicine with resulting dramatic reduction in the mortality and morbidity of most infectious diseases and to the contrasting essentially unchanged death rate from accidents. The situation reflects lack of information on the part of the laity and some apathy on the part of the medical profession. The lack of interest in the subject is the result not so much of inadequate information as of insufficient emphasis. THE JOURNAL has recently devoted two current comments on the subject. One of these[1] cited figures from the National Office of Vital Statistics: of 32,960 deaths from all causes in 1946 among persons 5 to 19 years old, 37 per cent (12,342) were caused by accidents, as compared with 35 per cent in 1945 and 34 per cent in 1941. The conclusion is inescapable that the greatest problem in preservation of lives of children is accident prevention.

According to Dr. Dietrich the problems of poliomyelitis, heart disease, cancer and tuberculosis in children are dwarfed by the physical and emotional devastation brought by juvenile accidents. In one year 12,500 children were killed by accidents. The number of children who were permanently crippled is not known, but Dr. Dietrich would place it at about 50,000 annually.

Dr. Wheatley[2] states that not only do accidents kill more children after infancy than does any single disease but, in the ages from 1 to 14, inclusive, accidents take as many lives as pneumonia, diarrhea and enteritis, measles, diphtheria, meningitis, poliomyelitis, whooping cough and scarlet fever combined. According to Clark,[3] the important causes of death due to diseases in the United States in the 1 to 14 year groups are pneumonia, congenital malformations, tuberculosis, heart disease and cancer. However, in numerical importance all these rank far below death from accidents. To cite one example, Dr. Clark states that the death rate from diphtheria for all ages has been reduced from 40.3 per 100,000 population in 1900 to 0.6 per 100,000 in 1947. In this same interval the death rate from accidents has fallen only from 72.3 in 1900 to 69.4 in 1947.

In the prevention of accidents it is worth taking note of the fact that some children are accident prone. This may have something to do with the accident proneness of their parents and with psychological problems in the children themselves. Psychiatric counseling is advisable in such cases.

Recent contributions to the subject emphasize that accidents do not happen but are caused, and since they are caused they can be prevented. Dr. Dietrich introduces a new idea into the subject of accident prevention in children. This theory emphasizes the reciprocal relation of protection and education related to a child's age. Prevention of a particular type of accident must employ varying protective and educational pressures at different ages. During the first year of life the prevention is protection: the infant should not be dropped or allowed to fall. The protection must be 100 per cent. As soon as the infant becomes ambulant the problem is more complicated. Here one must add to protection education against accident. The ultimate mediators of any accident prevention program in childhood are the parents. Children past the age of 1 year should be exposed to the educational value of minor painful experiences. The 1 to 5 year age period is the critical one so far as death and crippling are concerned.

A certain amount of discipline, Dietrich emphasizes, is valuable in the educational aspect of accident prevention. Discipline should play an important role not only in accident prevention but in character building of a child by enabling him to obtain a sense of security.

All workers in the field of prevention of accidents to children emphasize that the responsibility for the distribution of information to parents rests primarily on the medical profession. Specific information on the subject of accident prevention in children can be obtained from booklets published by several of the leading insurance companies. The importance of the problem was reflected in the discussions of the recent meeting in Chicago of the American Academy of Pediatrics. Dr. George M. Wheatley of New York was appointed to head a new committee that will attempt to reduce the number of accidents among the children of our nation. In the final analysis, it is the general practitioner who can contribute most to this subject, for it is he who should advise the parents on all matters pertaining to the health and safety of children.

ASSOCIATION OF MILITARY SURGEONS

Fifty-nine years ago, Nicholas Senn, a great surgeon, founded the Association of Military Surgeons of the National Guard. Dr. Senn, at that time Surgeon General of the Wisconsin National Guard, became the first president of this association. A few days ago in New York, the fifteenth president to be elected from the National Guard, Col. William Triplett of Baltimore, presided at the annual meeting and in his presidential address made a plea for physicians to offer their services to the National Guard. Colonel Triplett, who has devoted much of his life to this organization, knew of one regiment of the National Guard, whose history goes back to the Revolutionary War, that today has not a single doctor on its roster. The National Guard is important to the defense of this country, but its organization cannot be efficient or complete without the assistance of medical officers.

A brief review of the program at the New York annual meeting indicates the scope of activities this association now assumes. The opening session was privileged to hear representatives of the Army, Navy, Air Force, Public Health Service and Veterans Administration. The Director of Medical Services of the Department of Defense, Brig. Gen. Richard L. Meiling, pointed out that the military services should be able to provide the best medical services with a smaller ratio of physicians than was in use in the last great war. The Surgeon General of the Army, Major Gen. Raymond W. Bliss, who recently returned from Korea, reported that the medical services were doing an excellent job there under most difficult circumstances and that the mortality rate among the wounded was even less than in World War II. There was little serious disease among the troops. The Secretary General of the World Medical Association and Chairman of the Board of Trustees of the American Medical Association, Dr. Louis H. Bauer, reviewed some of the work which the World Medical Association has already accomplished and has under way. According to Dr. Howard A. Rusk, professor of physical medicine and rehabilitation, New York University—Bellevue Medical Center, the increasing average age of the population and the hazards inherent in present day living pose, perhaps, the greatest medical problem of the future in the field of rehabilitation. The present custom of retiring employees at a certain age, he said, is wasteful and deprives the nation of much of the wisdom that comes from experience. Dr. Rusk cited the recent retirement of the president of the largest corporation in the world and the almost immediate appointment of this executive to serve as ambassador in one of the most difficult positions of that kind. He recalled that the commander-in-chief of the Far Eastern forces is well past the customary retiring age and yet is vigorously prosecuting the war in Korea. The present system of having coroners determine the causes of sudden death was shown by Dr. Alexander Goettler, toxicologist to the Chief Medical Examiners Office of New York City, to be inadequate. Interesting cases of erroneous causes of death thus assigned revealed the need for thorough examinations by trained toxicologists in many cases of sudden death.

Capt. Lloyd R. Newhauser, U. S. Navy, in discussing a blood program in a national emergency was not in favor of mass blood grouping. When this method was tried on a large group in the Navy, he said, the errors amounted to about 10 per cent. The problems confronting the Council on National Emergency Medical Service of the American Medical Association were discussed by Dr. James Sargent, Council Chairman. These are derived from the necessity for planning for adequate military and civilian defense and from the Korean situation with respect to the procurement of physicians. Even the recently passed "doctor-draft law," while effective throughout the present program of expanding troop strength, is not a lasting answer to the needs of the Armed Forces for doctors. Special effort should be made by the medical schools, he said, to interest students in military medicine. Dr. Sargent proposed that machinery be set up through which those who are going into the service may be assured that their profession is genuinely interested in them, will give them council, will hear their complaints in confidence and will rectify them if just. He suggested that interested parties both in and out of service jointly help to accomplish a sensible revision of the whole system of our reserves. That, he said, calls for careful planning, in which there is "large room for civilian help."

The use of anticoagulants in military medicine and the selection of antibiotics for medical and surgical patients were discussed by Dr. Irving S. Wright, professor of clinical medicine at Cornell University, and Dr. Chester S. Keefer, professor of medicine, Boston University School of Medicine, respectively. Dr. William Stroud, professor of cardiology, University of Pennsylvania Graduate School of Medicine, interested the audience with his optimistic views of the treatment and prognosis of cardiovascular diseases.

Commanding officers sometimes pay a heavy price when they fail or refuse to follow the recommendations of the medical department. This fact was emphasized by Dr. Perrin H. Long, professor of preventive medicine at Johns Hopkins, who showed graphically the enormous increase of malaria in an armed force in Africa when troops, which had not followed the prophylactic measures recommended, entered certain malarial areas. This situation would be particularly distressing should the commanding officers themselves happen to be faddists or refuse to follow the recommendations of the medical department. Thus, the service of a large body of fighting men may be lost for a time. A supplementary report on dimenhydrinate (dramamine®), the surgery of World War III and the cold war were discussed by Dr. Leslie N. Gay, associate professor of medicine at Johns Hopkins, Dr. William

MacFee, surgical director, St. Luke's Hospital, New York, and Paul Linebarger, professor of Asiatic politics, School of Advanced International Studies, Washington, D. C., respectively. Professor Linebarger said that politics is unscientific and is now in a state comparable to the backward state that medicine was in hundreds of years ago.

In addition, the aviation corps panel, the medical services panel, the nurse corps panel, the dental corps panel and the veterinary corps panel each had its own sessions. Col. Amos R. Koontz, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, chairman of the program committee, is to be congratulated on arranging an excellent program.

The Association of Military Surgeons in the United States, which began as a National Guard organization, has expanded its membership to include the other uniformed services; to the annual meetings also come representatives from many of our neighboring countries. Its aims are to increase the efficiency of the medical services both in peace and war, to preserve lessons learned the hard way, to create new ideas for the better care of the sick and wounded and the prevention of epidemics. This middle-aged association is indeed vigorous. It welcomes new members to help keep it so.

COCKROACH VECTORS OF VIRUS DISEASE

Experimental evidence suggesting that under certain conditions cockroaches may serve as vectors of polioencephalomyelitis group viruses is reported by Syverton and Fischer[1] of the departments of bacteriology, universities of Minnesota and North Dakota.

Adult cockroaches were strapped to corks with adhesive tape. By means of a tuberculin syringe with a blunt needle, each cockroach was given a single feeding of 0.2 cc. of a 10 per cent suspension of brain tissue from a mouse dying from encephalomyelitis. The diet thereafter consisted of fox chow and water. Fecal specimens for each 24 hour period were collected daily.

Each 24 hour fecal sample was made up separately into a 1 per cent emulsion in saline solution containing 500 units of penicillin and 100 micrograms of streptomycin per cubic centimeter. After standing at room temperature for 30 minutes, each specimen was centrifuged, and 0.03 cc. of the supernatant fluid was injected intracranially into a normal 21 day old white mouse. Control injections were made with fecal material from normal cockroaches.

For each of the first six consecutive days after the experimental feeding the fecal suspensions contained sufficient virus to paralyze and kill mice in two to four days. On and after the seventh day, results of the tests were negative. All control mice remained normal.

Because of the gregariousness, longevity and nocturnal habits of cockroaches, and the intimacy and constancy of their association with the food and excreta of man and animals, this experimental evidence is of suggestive clinical interest.

AN ANTIBIOTIC FROM RED BLOOD CELLS

Whitney[1] and associates of the Department of Preventive Medicine, University of Texas, report the preparation of a new antibiotic from human red blood cells, which is active against a wide range of gram-positive and gram-negative bacteria. Recognition of antibiotics of animal origin is not new. As early as 1945, Konikova[2] of the Soviet Union prepared bacteriostatic extracts of rabbit liver and human placenta. Bloom,[3] Waksman[4] and others afterward isolated antibacterial peptides from other animal tissues. One of them was named "erythrin," since it was prepared from red blood cells. Pavan[5] of Italy afterward prepared antibacterial extracts from the tissues of helminths, arthropods, molluscs, fish, amphibia and reptiles.

To prepare the blood antibiotics the Texas biochemists drew blood samples from men, cattle, dogs, rabbits and chickens. These blood samples were allowed to coagulate. The clots were then separated from the serums, triturated in distilled water and lyophilized. The desiccated material thus obtained was suspended in phosphate buffer solution containing trypsin and incubated for five hours at 37 C. The digest thus obtained was then inactivated by heating to 65 C. for 30 minutes. Similar hydrolysates were made from commercial bovine hemoglobin powder. The resulting clear dark brown tryptic digests were tested quantitatively for antibacterial properties by spot dilution methods on glucose agar plates.

With the bovine blood antibiotic the tests showed complete growth inhibition for such organisms as Staphylococcus aureus, Sarcina lutea, Streptococcus viridans, Bacillus anthracis and Escherichia coli. There was a slightly less pronounced inhibition with human and canine blood antibiotics. Only partial inhibitions were recorded with chicken antibiotic. These antibiotics were nontoxic even when repeatedly injected intra-abdominally in large doses into mice or guinea pigs.

The antibacterial substances derived from erythrocytes resist exposure to 120 C. for 15 minutes at a p_H range of 7.8 to 9.0. At p_H 5.5 or lower they are precipitated. The authors believe that the active principle in blood antibiotics is a peptide-amino acid complex. Its relation to conventional immunity mechanisms has not yet been determined.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

As a result of the broadening sphere of influence of the American Medical Association in public affairs that affect the physical and economic well-being of the country, the President of the A. M. A. often has questions put to him by the press that are questions of public policy, rather than medical or scientific inquiries. One of the national press associations recently submitted a series of questions to me—some of which I would like to share with the readers of THE JOURNAL, as both the questions and my answers touch on matters of importance to our profession.

Here are a few of the questions and answers:

Q. Were doctors and/or their wives active in the election campaign?

A. The American Medical Association has not engaged in partisan politics for the election or defeat of individual candidates, but tens of thousands of doctors and their wives, acting as individual citizens, undoubtedly played a vital part in the recent elections. We believe this has been a healthy thing for the whole country and the medical profession would have been derelict in its duty if doctors had not fought for their convictions at the polls. It is paradoxical and somewhat amusing that those who now complain that doctors are too active politically were complaining just as loudly, only a few years ago, that the medical profession failed to take a proper interest in elections and public affairs. Undoubtedly one of the reasons that the medical profession was singled out as the first objective of those in the government who were determined on a program of socialization was that the advocates of Socialism felt that physicians could not or would not defend themselves when brought under attack. Fortunately, they erred in that diagnosis.

Q. Is the A. M. A. planning to "tone down" or intensify its drive against the Truman compulsory health insurance program?

A. There is no disposition on the part of American medicine to relax its vigilance or to relax its campaign against socialized medicine until the issue is finally resolved. The doctors of this country feel that there would be serious deterioration of medical care, endangering the health of the whole nation if physicians were regimented under political domination, and there will be no let up in medicine's fight so long as the danger exists. The American Medical Association also feels that the socialization of medicine in this country would be an irrevocable step toward a controlled economy and state socialism, which would affect not only physicians but people in every field of endeavor. We are determined to play our part in defending not only medical freedom but freedom for all Americans, and we are very proud of the role that doctors have played in awakening the American people to the seriousness of the trend toward socialization in this country.

Q. When and where do you look for the next big fight to come on this issue (socialized medicine) in Congress?

A. The Truman Administration, rather than American medicine, undoubtedly will determine what course the fight in Congress will take. So long as Federal Security Administrator Oscar Ewing remains in office, undoubtedly there will be continued efforts by his agency to enact compulsory health insurance in one form or another, but your questions in this regard probably should be directed to Mr. Ewing, rather than to us.

Q. Are doctors satisfied with the election results?

A. The returns of the November election were, in many respects, very reassuring to the medical profession, because they clearly demonstrated that those in the government who are urging that we follow in the footsteps of the Socialist government of Britain are out of step with the American people. We do not believe, however, that there is any cause for overconfidence or relaxing of vigilance. Both Mr. Ewing and the compulsory health insurance program that he advocates received a "thumbs down" verdict from the American people. But whether Mr. Ewing and his associates will accept the mandate of the people and admit that compulsory health insurance is looked on with disfavor by the majority of the people, we have no way of knowing. Again, perhaps you should ask Mr. Ewing. He may have some other explanation for the defeat of many members of the Congress who were outstanding exponents of his program of socialized medicine.

There were a good many other questions propounded, but most of them were the questions which many of you are asked constantly and which you can readily answer. One of the interesting aspects of all this to me is that there is a growing appreciation on the part of the press and national leaders that doctors have become alert, aggressive citizens—and that they are interested in the well-being of the country, as well as the health of their patients. We have our critics, of course, who feel embittered because we have successfully opposed those who had hoped to ride roughshod over the medical profession. But we have a new, fine group of friends, all over this country, who respect and admire us because we refused to accept the defeatist doctrine of the inevitability of government-controlled medicine—and struck out against it.

In this holiday season, as we near the end of the old year and face the problems and challenges of 1951, we have much to be thankful for, because we have earned a new measure of public confidence and public esteem, which is a great safeguard against those who would strip us of medical freedom. But because of the warm support we have achieved, we also have a great responsibility to the people of this country.

I would like to close this column by repeating as my pledge for the New Year, several lines from the Presidential Oath of Office that I took in San Francisco last June:

"I shall dedicate myself and my office to improving the health standards of the American people and to the task of bringing increasingly improved medical care within the reach of every citizen. I shall champion the cause of freedom in medical practice—and freedom for all my fellow Americans."

I hope every doctor will take that pledge with me.

ELMER L. HENDERSON, M.D.
Louisville, Ky.

WASHINGTON NEWS

(From the Washington Office of the American Medical Association)

Decentralization of Commissioning Authority

The Army has announced a speed-up of its procedure for granting reserve medical commissions. It amounts to a decentralization of commissioning authority, with Army area commanders in this country and overseas commanders authorized to grant commissions without reference to Army headquarters in Washington. The changes will be of greatest importance to registrants under the doctor-draft, who face the possibility of involuntary induction and loss of the $100 per month pay bonus. At the time the registrant reports for his physical examination he will be given an opportunity—the last as far as the Army is concerned—to apply for a reserve commission as a volunteer. If he accepts, his records will go immediately to the appropriate Army commander, who will determine the registrant's qualifications and mail him a letter of appointment if he is acceptable. The physician is instructed to take the oath of office within 72 hours of receipt of this notice. Then he is to notify his Selective Service Board of his commission. When the board is so informed, Selective Service will cease to process him for induction. If registrants take advantage of this system, the Army will complete its processing after the commissioning. The man will not be assigned to active duty until all regulations have been complied with, but meanwhile he will be assured a volunteer's status and the pay bonus. In the case of registrants who persist in refusing to accept commissions, records will be returned to their draft boards, rather than sent to Army commanders, when they complete their physical examinations. Draft boards then will list them as eligible for involuntary induction to meet calls from the armed services.

Physical Fitness of Reserve Officers

The Federal Register of November 21 carries detailed regulations covering appointment, reappointment and retirement of all Army reserves, including medical. The document may be purchased by sending 15 cents to the Superintendent of Documents, Government Printing Office, Washington, D. C. The regulations cover, in addition to physicians, medical service officers, nurses and medical technicians. For men now enrolled in the reserves the regulations have this to say about maintenance of physical fitness: "The maintenance of physical fitness is largely an individual responsibility, particularly with reference to remedial defects. Each officer has a definite obligation to maintain himself in good physical condition in order that he may perform his duties efficiently. Each individual, therefore, should seek timely medical advice if he has reason to believe that he has a physical defect which affects or is apt to affect his physical well being." Physical examinations by civilian physicians are authorized, but in this case the reserve officer himself must pay for the examination. As in the past, periodic physical examination of all reserve officers will be scheduled only when funds are available.

The New Congress

When the new congress meets, the administration will lose strength in committees as well as in total membership of House and Senate. For routine operations this is of little consequence. However, in the case of highly controversial legislation that has administration backing, the difference of one or two votes in a committee often is decisive. The realinement, which will be worked out in conference of party leaders in the next few weeks, might prove significant in several committees that handle almost all legislation of a medical or health nature. In the House, the Democrats will have no more than 236 votes, a loss of 24 votes for most roll calls. This should mean additional Republican seats on all large committees, including Armed Services, Expenditures in the Executive Departments and Interstate and Foreign Commerce. In the next two years all these committees will be handling legislation important to the medical profession. The armed services committee will consider extension of the doctor-draft and all other medical legislation involving the military services. The Expenditures Committee will hold hearings on government reorganization plans, including the proposal to make the Federal Security Agency into a cabinet department, if Mr. Truman again presses for this plan. The bulk of medical legislation—including national health insurance—comes within the province of the Interstate and Foreign Commerce Committee. In the Senate, about the same situation exists. There Republicans are in line for more voting power on such medically important committees as Labor and Welfare, Expenditures in the Executive Departments and Armed Services. At this stage speculation on individual committee assignments would be futile. Because in general House members are allowed to serve on only one major committee and senators on two, a great deal of shuffling and reshuffling will be required. There is a possibility that the session will be well under way before final committee lists are announced.

AEC Division of Biology and Medicine

Emphasis on civil defense planning is turning more attention toward the Atomic Energy Commission's Division of Biology and Medicine. The division has three broad fields of responsibility. It is expected to stimulate peacetime medical research through the use of radioactive substances, to devise technics for protecting the health of all persons working with radioactive material and to learn everything possible about the effects of atomic bombs on humans, animals and plants. Budget figures support the claim that the division is not expanding for expansion's sake. Although this year's appropriations for biology and medicine increased 26 per cent over last year's, the total AEC budget increased about 50 per cent. Division officials expect that their outside grants will level off at a figure only slightly in excess of this year's total, the actual rate depending largely on getting additional areas of research declassified. Once declassified, projects are open to any researcher. While in the secret classification, work must be carried on by AEC personnel or others who have undergone security checks. Although the division expects to continue to give general direction to research work, its primary responsibility narrows with each decision to declassify a certain project or phase of research.

For a time, the emphasis on security interfered seriously with AEC's research grants program. The National Research Council at first refused to administer the program as long as these restrictions prevailed, but now it is assisting to the extent of evaluating candidates. AEC's own Oak Ridge organization now administers the grants program. Unlike most government grant programs, the amount of money going to individual researchers and projects is not announced, although names of recipients are. AEC officials say the main reason for this secrecy is to avoid disclosing the primary research objectives. During the last full fiscal year, AEC invested about $17,500,000 in biologic and medical research, half for "on site" work in its own installations and the remainder as grants to outside researchers. A substantial share of the latter went for cancer research. AEC also sponsors a limited cancer research program at its own installations, including a 30 bed hospital at Oak Ridge.

The Medical Advisory Committee (Dr. Alan Gregg of the Rockefeller Foundation, chairman) does not allocate money but surveys progress in projects and makes recommendations as to fertile areas for investment of funds. It was a recommendation of this committee, incidentally, which recently caused AEC to step up its interest in the effect of radiation on the enzyme system. AEC's program for distribution of radioisotopes has brought the organization into direct contact with most large hospitals and schools. Isotopes are sent out at below cost—the $10 fee only helps to cover shipping costs. Because of this low cost, as well as other important advantages, the increasing use of isotopes is phenomenal. Domestic distribution the first six months of this year totaled 2,395, or 36 times that for the same period the previous year. Radiocobalt, particularly, is in great demand, and AEC officials expect that eventually it will completely replace radium in the treatment of cancer. The Isotopes Distribution Advisory Committee (Dr. G. Failla, Columbia University, chairman) must review all initial applications where the isotopes are intended for use on human beings. It also passes on other types of applications, but only when they are submitted to it by the commission.

In protection of personnel from excess radiation, the medical division and other groups associated with it have an almost perfect record. In the four years AEC has managed the program, there have been no deaths from radiation and only five injuries. Much of the work in this field is carried on by the Bureau of Standards in cooperation with AEC.

Although there have been no sensational discoveries, AEC is continuing its search for a specific treatment for radiation. One of its projects has established that aureomycin will decrease the mortality rate in rats and dogs exposed to lethal and near-lethal doses of radiation, and another, that a lead shield around the spleen will reduce the death rate of other experimental animals similarly exposed. Another project has shown that animals that inhale air composed largely of nitrogen prior to exposure may be expected to survive an otherwise lethal dose. Obviously this is just a start; out of this and other basic knowledge about radiation, researchers still must find a clew to a cure. Looking back on progress already made, AEC officials are sufficiently optimistic to state, "We are reasonably confident that eventually protection will be possible against midlethal doses and higher."

Cancer Control Facilities

The National Cancer Institute has issued a complete state by state and city by city summary of cancer control facilities, by far the most complete document yet assembled on the subject. The booklet is "Cancer Services and Facilities" (Public Health Service Publication no. 14) and is for sale by the Government Printing Office for 35 cents. It is intended as a source book, "particularly for those engaged in cancer control work or other activities affecting the cancer patient."

For each state the following information is supplied: citation of legislation under which state programs operate; agency in charge of program, its location and the name of its director; population statistics, including breakdown of white and nonwhite groups and of age groups; total number of cancer deaths for 1948 and breakdown of cancer locations; funds available, and source, for cancer work in that state; number of physicians and hospitals and hospital beds, and a description of special cancer facilities offered by that state. Following this, cancer clinics are listed by communities. Illinois, for example, has 46 cancer clinics, 20 of them located in Chicago and the rest in 24 other towns and cities.

The report underlines the extreme variation in sources of income for the programs as well as wide variation in the programs themselves. Because of large sums spent by some states for maintaining cancer hospitals and university research, an average for federal-state contributions would not be valid. However, here are some random examples of how the official programs are supported (all figures for the current fiscal year): Alabama is getting $77,353 from the federal government but is itself spending more than twice that; Connecticut is spending $83,230 of its own funds and collecting less than half that from the federal government; for every federal dollar Florida is getting, it is spending about six of its own; in Illinois, the ratio is about three federal dollars for every state dollar; Iowa spends almost seven federal dollars on cancer for each state dollar; Louisiana's ratio is about the same; Maryland is one of the states that operates on a relatively small federal allotment ($43,950) but spends no state money; Michigan is getting $123,095 from the federal government for its cancer program and is spending $9,360, a ratio of between 13 and 14 to one; Missouri is far at the other end of the scale, collecting $98,091 but spending $405,500 of its own funds; Delaware, likewise, finances most of its program, spending $50,000 as against $6,482 from the federal government. (All figures are from the Public Health Service report.)

Notes

A Defense Department spokesman says two factors helped to ease the demand for physicians: (1) an overestimate of casualties from the Inchon and Wonsan landings in Korea and (2) the Veterans Administration's action in agreeing to withdraw all but 790 of its patients from military hospitals. . . . Criticism of the doctor-draft has come from the Board of Regents, American College of Surgeons. In a letter to President Truman and top military medical officers, the board warned against waste of medical manpower and noted that casualties in the first four months of Korean fighting "were equal to only about one month's casualties in the United States from automobile accidents alone." . . . The Federal Security Agency has announced that it is prepared to help Israel to control disease and in general strengthen her public health facilities. The program will come under Point Four. . . . Dr. Don E. Nolan has been appointed manager of the new VA hospital in Seattle. He has been chief of Professional Services at the VA Dayton office. . . . Opened: VA 475 bed hospital at Wilkes Barre, Pa. Dedicated: VA 200 bed hospital at Altoona, Pa. . . . VA's latest technic for speeding service to veterans is a method of making facsimiles of roentgenograms. All original roentgenograms will be stored at the VA's Philadelphia Records Center, where, on request, facsimiles produced at a rate of one per minute by a solarization technic will be sent to hospitals or doctors treating veterans. . . . Alabama is the first state to receive federal funds to assist the permanently and totally disabled, a contribution authorized by amendments to the Social Security Act. The federal allotment will allow Alabama to boost its monthly payments from an average of about $11 per person to about $20. . . . The Government Printing Office has on sale the "Biographical Director of the American Congress," a monumental effort containing the names of the 9,942 persons who served in Congress along with short biographies. The book (2,057 pages) is crammed with important as well as incidental information about Congress. . . . The latest Public Health Grants for cancer total $324,525 and are divided among 17 projects. Under one grant, patients with lung cancer at several Massachusetts hospitals will be interviewed on smoking habits, exposure to occupational hazards, previous lung diseases, hereditary background and possible air impurities in their environment. The hope is that the various factors contributing to lung cancer will be isolated.

ORGANIZATION SECTION

THIRD ANNUAL MEDICAL PUBLIC RELATIONS CONFERENCE

Hotel Statler, Cleveland

Sunday and Monday, December 3 and 4

THEME: "EFFECTIVE COUNTY SOCIETY PUBLIC RELATIONS"

PROGRAM

Sunday, December 3

REGISTRATION

10:30 a. m., Euclid Room Foyer.

LUNCHEON

12:15 p. m., Euclid Room.

Toastmaster: Dr. George F. Lull, Chicago, Secretary and General Manager, American Medical Association.

Address of Welcome

Dr. George F. Lull

Keynote Address: Serve Your Profession Through Public Relations

Dr. John W. Cline, San Francisco, President-Elect American Medical Association.

GROUNDWORK FOR A SUCCESSFUL PR PROGRAM

2:15 p. m., Euclid Room.

Chairman: Dr. Cleo M. Miller, Nashville, Tenn., President, Nashville Academy of Medicine.

Who Directs the Work?

Dr. Russell B. Roth, Erie, Pa., Secretary, Erie County Medical Society.

Who Pays the Bills?

Mr. Arthur P. Tiernan, Evansville, Ind., Executive Secretary, Vanderburgh County Medical Society.

Finding the Sore Spots

Dr. John T. T. Hundley, Lynchburg, Va., President-Elect, Medical Society of Virginia.

Building the Program

Dr. Charles S. Lakeman, Rochester, N. Y., Chairman, Public Relations Committee, Monroe County Medical Society.

Enlisting the Membership

Dr. R. B. Chrisman, Miami, Fla., Secretary, Dade County Medical Society.

Questions and Discussion.

SPECIAL SCREENING

4:30 p. m., Euclid Room.

Promotion Comments

Mr. Lawrence W. Rember, Assistant to the General Manager, American Medical Association

Screening of "Here's Health"

(Louis de Rochemont's new documentary film.)

CONFERENCE BANQUET

6:30 p. m., Euclid Room.

Toastmaster: Dr. Louis H. Bauer, Hempstead, N. Y., Chairman, Board of Trustees, American Medical Association.

Introduction of Special Guests

Dr. Louis H. Bauer

Salute to County Societies

Dr. Elmer L. Henderson, Louisville, Ky., President, American Medical Association.

What the Community Expects of the Medical Profession

Mr. Louis B. Seltzer, Cleveland, Editor, Cleveland Press.

Monday, December 4

COUNTY SOCIETIES AND THE LEGISLATIVE SCENE

9:15 a. m., Euclid Room.

Chairman: Dr. Gunnar Gundersen, La Crosse, Wis., Chairman, Executive Committee, Board of Trustees, American Medical Association.

The Legislative Committee and You

Dr. Dwight H. Murray, Napa, Calif., Member, Board of Trustees, Chairman of Committee on Legislation, American Medical Association.

What's Ahead in Washington

Dr. Joseph S. Lawrence, Washington, D. C., Director, Washington Office, American Medical Association.

Questions and Discussion.

ACTIVITIES WITH A PURPOSE

10:00 a. m., Euclid Room.

Chairman: Mr. Rollen W. Waterson, Oakland, Calif., Executive Secretary, Alameda County Medical Society.

A Family Doctor for Every Family

Dr. Eugene A. Ockuly, Toledo, Ohio, President, Toledo Academy of Medicine.

Community Health Projects

Dr. Fred Sternagel, West Des Moines, Iowa, Chairman, Committee on Medical Service and Public Relations, Iowa State Medical Society.

PR Approach to Business Methods

Dr. E. L. Bernhart, Milwaukee, President, Medical Society of Milwaukee County.

Working with Other Health Professions

Dr. William M. Skipp, Youngstown, Ohio, Mahoning County Medical Society.

Promoting Voluntary Health Insurance

Dr. Carl F. Vohs, Clayton, Mo., President, Missouri Medical Service.

The Doctor and Civilian Defense

Dr. Frederic B. Davies, Scranton, Pa., Committee on Emergency Disaster Medical Service, Medical Society of State of Pennsylvania.

Questions and Discussion.

LUNCHEON

12:15 p. m., Grand Ballroom.

Toastmaster: Dr. F. F. Borzell, Philadelphia, Speaker, House of Delegates, American Medical Association.

What IS This American Way?

Mr. R. W. Mills, Fond du Lac, Wis., Executive Secretary, Fond du Lac Association of Commerce.

THE IDEA EXCHANGE

2:15 p. m., Euclid Room.

General Chairman: Dr. G. A. Woodhouse, Pleasant Hill, Ohio, Secretary-Treasurer, Miami County Medical Society. (After remarks of the general chairman, conferees will assemble in three groups to take up separate medical public relations problems of small, medium and large communities.)

Group 1: Medical Public Relations in a Small Community (Under 100,000)

Discussion Leader: Dr. G. A. Woodhouse.

Group 2: Medical Public Relations in a Medium-Sized Community (100,000-500,000)

Discussion Leader: Dr. John E. McDonald, Tulsa, Okla., Public Policy Committee Chairman, Oklahoma State Medical Society.

Group 3: Medical Public Relations in a Large Community (Over 500,000)

Discussion Leader: Dr. Arch Walls, Detroit, President-Elect, Wayne County Medical Society.

4:15 p. m., Euclid Room.

Report of Discussion Group Chairmen.

4:45 p. m., Adjournment of Conference.

GOVERNMENT SERVICES

Navy

Edward Rhodes Stitt Library

The medical library of the Naval Medical School at the Naval Medical Center, Bethesda, Md., has been renamed the Edward Rhodes Stitt Library in recognition of Admiral Stitt's distinguished service in the field of tropical medicine and as Surgeon General of the U. S. Navy from 1920 to 1928. The principal speakers at the ceremony were Rear Admiral Morton D. Willcutts, commanding officer, Naval Medical Center, and Capt. Bartholomew W. Hogan, commanding the Naval Medical School.

Guest Lecturers

Dr. Waltman Walters, chief of surgery, Mayo Clinic, Rochester, Minn., opened the current series of guest lectures at the Naval Medical School, Bethesda, Md., September 29, when he discussed "Surgery of the Stomach with an Evaluation of Vagotomy." Dr. A. R. Shands Jr., Wilmington, Del., was the guest lecturer at the Naval Medical School, Bethesda, Md., on October 27. His subject was "Some of the Problems of the Hip in Childhood." These meetings are open to members of the local medical societies and faculties of local medical schools, as well as medical officers of the Armed Forces, Public Health Service, Veterans Administration and Indian Affairs Bureau.

Deputy Director of Institute of Pathology

Capt. Arthur W. Eaton (MC, USN) has been appointed Deputy Director of the Armed Forces Institute of Pathology, Washington, D. C. Captain Eaton's entire medical career has been in the field of pathology, with the exception of three years during World War II, when he served in the Pacific Area with the 7th Fleet, the Amphibious Training Command and the Third Amphibious Force. He was an instructor in pathology at the U. S. Navy Medical School in 1937 and subsequently was pathologist on the hospital ship *USS Relief* and at several Navy hospitals.

Personal

Lieut. Col. Theodore M. Carow (MC), deputy chief of the Armed Services Medical Procurement Agency in Brooklyn, has been promoted to the rank of colonel. The 43 year old Army doctor is the youngest officer ever to occupy the deputy chief's position at the agency.

Capt. Charles W. Lane (MC, USNR) on October 16 became director of the Bureau of Medicine and Surgery's Naval Reserve Division. Captain Lane has been in the naval service for over 33 years, nearly 20 of which have been on active duty. He was in private medical practice in San Diego for 14 years.

Public Health Service

Examination for Scientists

A competitive examination for appointment of bacteriologists, entomologists, parasitologists and protozoologists to the Regular Corps of the United States Public Health Service will be held February 12-14, 1951 at points throughout the United States. Applications must be received no later than January 15, 1951. Appointments will be made in the grades of assistant scientist and assistant sanitarian (equivalent to Navy rank of lieutenant, j.g.) and senior assistant scientist and senior assistant sanitarian (equivalent to lieutenant). While consideration is given to the officer's preference, ability and experience, all commissioned officers are subject to change of station and assignment as necessitate the needs of the service. Appointments are permanent in nature and provide opportunities for qualified bacteriologists to pursue their profession as a life career in the research and public health activities. The names of applicants who successfully complete the examination will be placed on a merit roll, from which appointments will be made to fill current and future vacancies. Candidates must be United States citizens and at least 21 years of age. Application forms may be obtained from the Surgeon General, United States Public Health Service, Federal Security Agency, Washington 25, D. C., Attention: Division of Commissioned Officers.

Research on Diabetes and Personality

The National Institute of Mental Health of the Public Health Service has made a grant of $7,884 for a three year study on the psychodynamics of persons with potential diabetes mellitus to be conducted at the May Institute for Medical Research, Cincinnati, under the direction of Dr. I. Arthur Mirsky. The announcement by the Public Health Service states that prediabetics can often be identified through their medical histories, and recent studies indicate that a person in whom diabetes develops has a personality structure different from that of the nondiabetic. The study will cover the mental, emotional and physical makeup of a group of prediabetics before they actually become ill. The announcement further states that the study may reveal the conditions related to the development of diabetes and, "it is hoped," may eventually help in the discovery of preventive measures. This grant was one of 21 new mental health research grants approved by Surgeon General Leonard A. Scheele on recommendation of the National Advisory Mental Health Council, which, in addition to renewal of 44 earlier grants, makes a total of $855,740 approved for mental health research.

Latin American Fellows

Ten physicians, nurses and other health workers from Latin American countries are in the United States for one year of advanced training under programs supervised by the Division of International Health of the Public Health Service. Fellowships for the training are provided by the Educational Exchange Act. Among the trainees are:

Dr. Alexander G. Cevallos, chief of Maternal and Child Health Services of the Health Department, Province of Manabi, Ecuador; to study treatment and control of tuberculosis at the Herman Kiefer Hospital, Detroit.

Dr. Alcides L. Conti, head of the Dermatology and Syphilology Clinic, Policlinical Hospital, La Plata, Argentina; to study dermatology and syphilology at New York University.

Dr. Jose Horowitz, neuropsychiatrist, Santiago, Chile; to study mental hygiene and public health at Johns Hopkins University.

Dr. Simon Markovich, head of the Department of Neurophysiology, University of Chile, Santiago; to study neurophysiology at Columbia University.

Dr. Jose Manuel Ortega, surgeon at the Huipulco Municipal Hospital; to study thoracic surgery at Fort Sanders Hospital, Knoxville, Tenn.

Dr. Jose Sosa, professor of bacteriology and immunology, National School of Biological Sciences, Mexico City; to study virus diseases and public health at the University of California, Berkeley.

MEDICAL NEWS

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Jacob Gimbel Lectures.—Dr. Manfred S. Guttmacher, chief medical officer, Supreme Bench of Baltimore, delivered the Jacob Gimbel lectures under the auspices of Stanford University and the University of California November 27-December 1 at the Stanford University School of Medicine, Berkeley-San Francisco. The subject of this year's lectures was sexual offenses. Dr. Guttmacher spoke on the clinical aspects and treatment, medical and legal. He also spoke at both Stanford University and the University of California November 28-30 on the sexual offender.

Chronic Disease Program.—After two years of study by a committee organized by the Social Planning Committee of the Community Chest, funds have been secured from a private source and a director appointed to take the first steps in the pooling of resources to meet the needs of the chronically ill of San Francisco. Information will be made available through meetings, brochures and reports, and research information and occupational therapy, rehabilitation and home care programs will be planned. A sound working relation will be developed with physicians, hospitals, nursing organizations and nursing homes, the health departments and educational and civic groups. The Community Chest will serve as a disbursing agent and provide some services. Mrs. Helene M. Lipscomb, who has had experience with community services in California and eastern cities, is the director. Her office is at 2015 Steiner Street in the Community Chest Building. The telephone number is Walnut 1-7032.

COLORADO

Survey of Arkansas River Basin.—A survey to determine the extent and cause of pollution of the Arkansas River Basin was begun in October to bring up to date previously collected information and to publicize the need for treatment of domestic and industrial wastes. The study is a cooperative program of the Colorado State Department of Game and Fish and the State Department of Public Health. Temporary laboratory facilities will be arranged in Salida, Pueblo, La Junta, Trinidad, as well as in established laboratories in Denver, to conduct tests of samples of water taken the entire length of the river and its principal tributaries. Samples will be taken above each town, at the point of sewage outfall, at the point of induction of any industrial waste and below the town. Samples will be taken over a period of several months to obtain a true picture of the extent of stream pollution in the area of each community and industry.

ILLINOIS

Chairman of Cancer Society Committee.—Dr. Walter G. Maddock, Chicago, Elcock professor of surgery at Northwestern University Medical School, has been elected chairman of the Medical and Scientific Committee of the Illinois Division, American Cancer Society, Inc., for 1950-1951. The committee, composed of 52 Illinois physicians and scientists, is responsible for the division's medical and scientific policy, including research, education and service. It reviews all professional activities and projects and recommends appropriations to the executive committee of the society. Dr Maddock also represents Northwestern University Medical School on the division's Professional Education Committee, which conducts cancer refresher courses with the cooperation of the medical schools of the universities of Chicago, Illinois and Loyola.

Chicago

Furniture Dealers Aid Cancer Research.—The Albert G. Joseph Cancer Research Foundation has presented a check for $25,000 to help support cancer research at the University of Chicago. The gift was presented at a dinner at the Stevens Hotel November 14. Speakers included Dr. Lowell T. Coggeshall, dean of the university's division of biological sciences, and Dr. James W. J. Carpender, assistant professor of radiology. The foundation, organized in memory of Albert G. Joseph, active in the furniture business in Chicago from 1911 until his recent death from cancer, is supported by contributions from more than 500 retail furniture men and dealers in allied businesses.

Grant Hospital Affiliates with University.—An affiliation has been arranged between Grant Hospital and the University of Illinois College of Medicine for the purpose of stimulating clinical teaching and organized research programs at both institutions. Members of the present staff at Grant Hospital will continue in their present capacities and new appointments will be correlated by the university and the hospital. The board of directors of Grant Hospital will retain all of its present authority over the administrative, physical and professional aspects of the hospital. The university will have representation on the board. The hospital has 236 beds for adult patients plus 45 bassinets. Grant also operates an outpatient clinic, which had 17,720 patient visits during 1949. Of that number, 10,296 visits were handled at no cost to the patient.

KENTUCKY

Research on Childhood Infections.—A virus research laboratory which will concentrate on childhood infections has been established at the University of Louisville School of Medicine. Its completion was effected by a grant from the recently organized Kentucky Child Health Foundation. The investigations will be supervised by Dr. Alexander J. Steigman and James G. Shaffer, Sc.D., of the school's child health and bacteriology departments.

Dr. Bortz Addresses Dinner Meeting.—At the monthly dinner meeting of the Jefferson County Medical Society in Louisville November 20, the guest speaker was Dr. Edward L. Bortz, associate professor of medicine, Graduate School of Medicine, University of Pennsylvania, Philadelphia, and Past President of the American Medical Association, whose subject was "Diabetes Today and Tomorrow." The address was sponsored by the Louisville Society of Physicians and Surgeons.

Crippled Children Society.—The annual meeting of the Kentucky Society for Crippled Children was held in Lexington November 10. At the morning session reports were given of projects initiated by the society. Lawrence J. Linck, executive director, National Society for Crippled Children and Adults, Inc., Chicago, addressed the luncheon meeting. At 2:30 p. m. the Honorable Earle C. Clements, governor of Kentucky, and other distinguished persons were guests of the society at the dedication of the new convalescent home one mile from Lexington.

MARYLAND

Personals.—Dr. Robert E. Bauer has been named medical director of the Sharp & Dohme Blood Donor Center in Baltimore. He has recently been a resident at University Hospital in Baltimore.

Society News.—The Maryland Society of Pathologists elected the following officers for the ensuing year: Dr. Harold L. Stewart, Bethesda, president; Dr. Carroll G. Warner, Baltimore, vice president, and Dr. Russell S. Fisher, Baltimore, secretary-treasurer.——Dr. John K. Lattimer, New York, addressed the fall meeting of the Urological Section of the Medical and Chirurgical Faculty of Maryland October 19 in Baltimore, on "Tuberculosis of the Urogenital Tract."

Dr. Ivy Delivers Friedenwald Memorial Lecture.—Dr. Andrew C. Ivy of the University of Illinois gave the fifth annual Dr. Julius Friedenwald Memorial Lecture on November 2 at the University of Maryland School of Medicine, Baltimore, on "Physiological Basis of the Psychosomatic Aspects of Peptic Ulcer." This lectureship was established at the university in 1941 in honor of Dr. Friedenwald, formerly professor of gastroenterology.

MASSACHUSETTS

New Division of Alcoholism.—An attack on the problem of the state's chronic alcoholics was launched November 16 with creation of a new Division of Alcoholism in the State Department of Public Health. On the same day the first of two clinics for rehabilitating alcoholics was opened under department sponsorship at the Peter Bent Brigham Hospital, Boston, and at the Quincy City Hospital. Director of the new division will be Dr. John C. Ayres of Brighton, at present assistant director of the department's Division of Communicable Diseases. The new division's attack is aimed at (1) diagnosis, treatment and rehabilitation of persons addicted to the excessive use of alcohol, (2) prevention and education and (3) research in the medical and public health aspects of chronic alcoholism. The division will operate with a limited budget of $40,000 to cover costs until June 30, 1951. The division is expected to work in conjunction with other agencies, such as Alcoholics Anonymous, committees for education on alcoholism, church and other groups. The state's alcoholism rate ranks fifth in the nation. Dr. Vlado A. Getting, state health commissioner, declared that the cost to governmental agencies for incarceration of problem drinkers and care of their families is estimated by the legislative Commission on Alcoholism at $61,000,000 annually. In setting up the Division of Alcoholism, Massachusetts is following the lead of Virginia, New Jersey and Pennsylvania in treating alcoholism as a part of its general public health program. Governor Dever signed the bill providing for the state program on August 17.

MICHIGAN

Prenatal Clinic.—A clinic to provide antepartum care and home delivery for the medically indigent has been set up in Oakdale Gardens, an area where the death rate at birth is highest in Oakland County. It will serve about 15,000 persons and will be educational as well as medical, providing instruction for *prospective mothers on how to care for themselves and their* children. Located in Oakdale Community Center, the clinic will be open from 1:00 to 2:00 p. m. on Tuesdays and at additional times as the project becomes better known. Cooperating groups, brought together through the Council of Social Agencies, are furnishing funds and personnel. These groups include Family Service of Oakland County, Visiting Nurses, Federal Housing Authority, Oakland County Social Welfare Board, the state and county health departments and the U. S. Children's Bureau in Washington.

NEW MEXICO

Lovelace Foundation Clinic Dedicated.—Dedication ceremonies for the Lovelace Foundation's million dollar clinic building were held November 4 at Albuquerque. The state governor, both senators and more than 1,000 others attended. Among the speakers were Dr. Ward Darley Jr., dean, University of Colorado School of Medicine, Denver; Dr. Charles W. Mayo, Rochester, Minn.; Dr. George F. Lull, Secretary and General Manager, American Medical Association, Chicago; Senators Clinton Anderson and Denis Chavez, and Mr. Floyd Odlum, chairman, board of directors of the foundation. Open house was held at the new building after the dedication. Ground-breaking ceremonies for the 110 bed Bataan Memorial Hospital being built by the Methodist Church on ground adjoining the clinic also were held. The clinic is situated north of the Veteran's Administration Hospital, which is now completing a $3,200,000 addition that will bring its capacity to 591 beds. Members of the clinic staff act as consultants at the veterans hospital.

Construction of the four story building began in June 1949. Trans World Airlines has furnished a laboratory for respiratory and circulatory studies of pilots. The library contains more than 5,000 volumes as well as 250 medical and surgical journals. The Lovelace Clinic was founded in 1922. In 1947 it turned over its entire assets plus its future net income to the Lovelace Foundation for Medical Education and Research.

NEW YORK

Dr. Seed Promoted at Research Institute.—Dr. John C. Seed, formerly with the Army Chemical Center in Edgewood, Md., has been appointed executive assistant to Dr. Maurice L. Tainter, director of the Sterling Winthrop Research Institute, Rensselaer. Dr. Seed's duties include liaison between the institute and the medical profession. He interned at the Massachusetts General Hospital until entering the Army in April 1946. There he supervised and conducted research at the Army Chemical Center. On release from the service he continued similar duties as a civilian employee until his arrival at the institute.

Rochester Academy Anniversary.—The Rochester Academy of Medicine celebrated its fiftieth anniversary at a dinner at the Oak Hill Country Club in October. The speaker was Dr. George W. Corner, director, department of embryology, Carnegie Institute in Baltimore, who spoke on medical education and practice in the days of Benjamin Rush. Supplementing the program was a portrait exhibit by the Museum Committee in the foyer of the club. Included were large photographs of three doctors who formed the academy, William S. Ely, John O. Roe and Edward B. Angell, as well as a portrait of another founder, Dr. Louis A. Weigel, an early worker in the field of roentgen therapy.

Stockpile Medical Supplies.—A $500,000 emergency appropriation for the stockpiling of medical supplies and equipment for use in the event of enemy attack has been approved for use of the State Civil Defense Commission. The appropriation is expected to "stimulate the production of essential supplies," which will be primarily drugs and antibiotics. They are to be stored in strategically located state institutions. The state will purchase also surgical kits, blood transfusion sets, fracture supplies, burn treatment supplies, syringes and needles. The State Department of Health and the Civil Defense Commission will order and arrange for storage of the material. Staffs are now being trained for its use.

New York City

Hospital News.—Construction of several new units for Mount Sinai Hospital was announced in November with the letting of a contract totaling approximately $6,000,000. The buildings include the Berg Institute of Research, a maternity pavilion, a laboratory building and a new x-ray department, as well as alterations and additions to the existing hospital.

Named to Cancer Institute Board.—Detlev W. Bronk, Ph.D., president of Johns Hopkins University, Baltimore, and Rear Admiral Lewis L. Strauss, Washington, D. C., have been elected to the board of trustees of Sloan-Kettering Institute for Cancer Research. Dr. Bronk is president of the National *Academy of Sciences, member of scientific directors of the* Rockefeller Institute for Medical Research and serves on the committee of biology and medicine of the Atomic Energy Commission. Admiral Strauss, until recently a member of the Atomic Energy Commission, is president of the Institute for Advanced Study in Princeton and a member of the Naval Research Advisory Committee and the board of managers of Memorial Center for Cancer and Allied Diseases.

Postgraduate Radio Programs.—The sixth of the New York Academy of Medicine's FM radio broadcasts "For Doctors Only" will be initiated on December 7 at 9:00 p. m. over station WNYC-FM with an address by Dr. Cyril N. H. Long, dean, Yale University School of Medicine, New Haven, Conn., on "Pituitary-Adrenal Relationship." Other scheduled programs are as follows:

Dec. 14, Alexander B. Gutman, New York, Gout.
Dec. 21, Robert H. Kennedy, New York, Chairman, Roundtable: Sport Injuries.
Dec. 28, Joseph J. Bunim, Brooklyn, Clinical Effects of Cortisone and ACTH in Rheumatic Diseases.
Jan. 4, Charles A. Ragan, New York, Rheumatoid Arthritis: The Natural History of the Disease and Its Management.

The response to the broadcasts has been widespread and enthusiastic.

Medical Aspects of Compensation.—A course under this title is being presented by New York University-Bellevue Medical Center in collaboration with the American Academy of Compensation Medicine December 4-9 at Erdmann Auditorium from 1:00 to 4:00 p. m. and 7:00 to 10:00 p. m. The tuition is $25. The roundtables and their moderators are as follows:

Peripheral Vascular Problems in Compensation Medicine, A. Wilbur Duryee.
The Heart and Compensation Medicine, Cary Eggleston.
Radiology in Relation to Compensation Medicine, A. L. Loomis Bell.
Surgery in Relation to Compensation Medicine, Harry V. Spaulding and Francis B. Berry.
Gastrointestinal Diseases, Z. Taylor Bercovitz.
Genitourinary Diseases in Relation to Compensation Medicine, Robert W. Hunt.
Rehabilitation, Howard A. Rusk.
Occupational Diseases, Paul Reznikoff.
Problems in Practical Applications of Radiation and Radioactive Materials, Bernard S. Wolf.
Ophthalmology in Compensation Medicine, Conrad Berens.

Tuberculosis High in Manhattan.—The borough of Manhattan leads the city in tuberculosis mortality. The New York Tuberculosis and Health Association reports that during the first six months of 1950 about half (610) of the 1,264 deaths from tuberculosis in New York City were of residents of Manhattan. Of the 4,226 new cases of tuberculosis registered in the city during this period, 2,075 were in residents of Manhattan. In relation to the population of the various boroughs as just enumerated by the Census Bureau, the registration of new cases of tuberculosis in the City of New York during the first half of 1950 averaged 107.7 per 100,000 population. The average for Manhattan was 213.9. The cost of maintenance and care for victims of the disease in New York City is more than $34,000,000 a year. This figure ignores expenditures for relief and loss of wages by the adults who have been stricken. It also makes no allowance for the contributions made by a large number of physicians, especially tuberculosis specialists, who give their services free for the care particularly of patients in public institutions.

PENNSYLVANIA

Medical Careers Conference.—A total of 442 high school students attended a Medical Careers Conference at St. Vincent's Hospital, Erie, sponsored by the Erie County Medical Society November 8. Officers of the society outlined the purpose of the conference. Nursing was the subject attracting the largest number of students. A possible career in medicine inspired the attendance of the second largest group. Dr. Joseph M. Walsh, Erie, chairman of the medical society committee which arranged the conference, declared the unexpected enthusiasm of the high school students illustrates the usefulness of having other similar conferences.

Philadelphia

Dr. Bennett Becomes Dean at Jefferson.—Dr. William H. Perkins has resigned as dean of Jefferson Medical College because of his health. He will continue his position as professor of preventive medicine and head of the department. Dr. George A. Bennett, professor of anatomy, head of the department and director of the Daniel Baugh Institute of Anatomy, has been given additional duties as dean of the college. He has been a member of the faculty for 11 years. He was professor of anatomy and acting head of the department of anatomy at Georgetown University prior to joining the faculty of Jefferson.

Pittsburgh

Dr. Hamor to Receive Award.—William A. Hamor, LL.D., assistant director of Mellon Institute, has been named by the Pittsburgh Section of the American Chemical Society to receive its Pittsburgh Award for 1950. The award will be presented at a dinner in the University Club of Pittsburgh on December 21. Dr. Hamor has served on several governmental agencies and is a member of the Research Advisory Council of the Industrial Hygiene Foundation of America.

SOUTH DAKOTA

University News.—Dr. Ralph L. Ferguson, head, department of pathology, University of South Dakota School of Medical Sciences, Vermillion, resigned, effective November 1, to go into private hospital work in pathology in Joplin, Mo. Dr. Ferguson came to the university in 1945.

TEXAS

McReynolds Lecture in Ophthalmology.—The annual John O. McReynolds Lecture in Ophthalmology was given by Dr. Arlington C. Krause of the University of Chicago at the University of Texas Medical Branch, Galveston, November 6. Dr. Krause discussed some of his recent experimental studies on eye injury.

Rheumatism Association Meeting.—Dr. Richard H. Freyberg, associate professor of clinical medicine at Cornell University Medical School, New York, will be the honor guest at the Texas Rheumatism Association at the Shamrock Hotel, Houston, December 8. He will speak on "Practical Considerations in the Use of ACTH and Cortisone in Rheumatic Disease."

Committee on Skin Regeneration.—A special committee on skin metabolism and regeneration has been established at the University of Texas Medical Branch, Galveston, to correlate studies in these fields with particular reference to the management of burns and radiation injury. The chairman of the committee is Dr. Clarence S. Livingood, professor of dermatology and syphilology. The members of the committee include Dr. Truman G. Blocker Jr., professor of plastic and maxillofacial surgery; Charles M. Pomerat, Ph.D., director of the Tissue Culture Laboratory; Kenneth McConnell, Ph.D., director of the laboratory of medical physics, and Dr. Arild E. Hansen, professor of pediatrics.

VIRGINIA

Children's Service Center Moves.—The Children's Service Center, established in 1948 at the University of Virginia Department of Medicine, Charlottesville, as a child guidance clinic under the direction of Dr. Frank J. Curran, associate professor of neurology and psychiatry, has moved from the University of Virginia Hospital to larger quarters in the neighborhood. The center has a staff of 10.

WISCONSIN

Shortage of Animals for Research.—The regents of the University of Wisconsin November 11 took action to overcome the "unnecessary shortage" of dogs for teaching and research. They requested the state attorney general to take action to obtain compliance with the state law requiring that humane societies turn over stray dogs to the medical schools at the University of Wisconsin and Marquette University. Dr. Harold M. Coon of State of Wisconsin General Hospital said that material for third-year medical students taking surgery is not available to meet ordinary teaching needs. "The question is," he continued, "shall the laws of the state of Wisconsin be flouted by a small number of antimedical people and thereby hinder the teaching of medical students and the training of doctors for which there presently is a great need."

Memorial Lecture on Allergy.—Alpha Omega Alpha of the University of Wisconsin Medical School, Madison, will present a lecture in honor of the late Dr. William A. Mowry in the auditorium of Service Memorial Institutes at 8:00 p. m. December 7. Dr. Carl A. Dragstedt, professor of pharmacology at Northwestern University Medical School, Chicago, will speak on, "A Pharmacologist Looks at Allergy."

CANAL ZONE

Society News.—At the October meeting of the Medical Association of the Isthmian Canal Zone at Colon Hospital, Cristobal, the staff of Colon Hospital presented the scientific program. Dr. W. W. Jackson spoke on "Metal Fumes Fever." A paper prepared by Dr. Frank E. Riefkohl on "Infantile Scurvy on the Isthmus of Panama" was read, as was a paper by Dr. Pickney on "Differential Diagnosis of Splenomegaly."

GENERAL

Southern Surgical Association.—This association will hold its annual meeting at the Hollywood Beach Hotel, Hollywood, Fla., December 5-7, under the presidency of Dr. George V. Brindley, Temple, Texas. A series of 40 papers will be presented.

Southern Psychiatric Association.—This association held its annual meeting November 27-28 at the Williamsburg Inn, Williamsburg, Va., under the presidency of Dr. R. Finley Gayle Jr., Richmond, Va. Guest speakers included Dr. Trevo C. N. Gibbens, Institute of Psychiatry, London University, England, who spoke on "Notes on Psychiatrists' Attitudes," and Dr. Patrick H. Tooley, University of London, England, visiting professor of psychiatry, Bowman Gray School of Medicine, Winston-Salem, N. C.

Board of Ophthalmology Examinations.—Candidates for the certificate of the American Board of Ophthalmology are accepted for examination on the evidence of a written qualifying test held annually, in January, in various parts of the United States. Applications for the 1952 written test must be filed before July 1. Ninety-eight examinations have been held to date. Certificates issued total 3,143. The 1951 examinations will be held in San Francisco March 11-16, in New York May 31-June 5 and in Chicago October 8-13. Dr. John H. Dunnington, New York, is chairman of the board and Edwin B. Dunphy, Boston, is secretary-treasurer. The executive offices are at 56 Ivie Road, Cape Cottage, Maine.

Nutrition Foundation.—At its annual meeting November 16 at the Waldorf-Astoria Hotel in New York, the Nutrition Foundation, Inc., made grants-in-aid for research totaling $129,850. Contributions to the foundation, supported by 56 food manufacturers and related industries, total $350,000 annually. Contributions since 1942 when it was organized have amounted to over $4,000,000. The foundation is presently supporting basic research concerning the relation of food to anemia, bone formation, cancer, dental caries, diabetes, heart and vascular diseases such as hardening of the arteries, high blood pressure, glandular functions and infant health. Eight renewals of grants-in-aid and a like number of new applications were approved.

Dr. MacEachern Retires from College of Surgeons.—Officers, regents and the administrative staff of the American College of Surgeons held a dinner in Chicago November 19 in honor of Dr. Malcolm T. MacEachern, director emeritus of the college, on the occasion of his retirement. Dr. MacEachern began his service with the American College of Surgeons in August 1923 as director of hospital activities. From 1935 to 1949 he was associate director and chairman of the administrative board. In 1949 he was appointed director. In March 1950 he assumed his present title of director emeritus, and was succeeded as director by Dr. Paul R. Hawley. He remained in charge of the hospital activities of the college until the end of October. Dr. MacEachern will continue his duties as professor and director of Northwestern University's program in hospital administration, which he established in 1943. He is considering other activities. Among other honors, Dr. MacEachern received in 1939 the Award of Merit of the American Hospital Association; in 1948 the Gold Key of the Tri-State Hospital Assembly; in 1949 a Gold Key, diamond set, from the Association of Western Hospitals; in March 1950 the Winnipeg City Crest, and in October 1950 a citation from the New England Hospital Assembly and the Massachusetts Hospital Association for his 27 years of service to hospitals.

Fellowship Committee of Medical Association of Israel—A group of American physicians, whose purpose is to strengthen the relation between Israelian and American medicine and to maintain the dignity and prestige of the physicians in Israel, has nearly 700 members and has been named the American Physicians Fellowship Committee of the Medical Association of Israel The Israel Medical Association which comprises 97 per cent of all physicians in Israel, is backing this organization Members of this organization automatically become nonresident fellows of the Israel Medical Association and receive the medical quarterly of the Israel Medical Association, *Harefuah,* as well as an engraved membership diploma and card The dues are $10 yearly Applications will be received at 273 Main Street Nashua, N H The officers of the committee are Dr Morton J Robbins, Nashua N H, president, Dr Julius M Rogoff, Pittsburgh, honorary president, Dr Manuel M Glazier, Boston, secretary, and Dr Leon B Schwartz Bronx, N Y, treasurer

Mid-South Meeting of College of Physicians—A regional meeting of the American College of Physicians including Louisiana, Texas, Tennessee and, by invitation, Alabama, Arkansas and Mississippi will be held at the Peabody Hotel Memphis, Tenn, January 12-13 beginning at 1 30 p m Invited speakers include

Lemuel W Diggs Memphis, Tenn, The New Nomenclature for Blood Cells
Arthur C Guyton, University, Miss, Studies on Controlled Acute Cardiac Failure
Charles H Burnett, Dallas, Texas, Adrenal Pituitary Relationships in Renal Function

Other guests will be Dr G Morris Piersol, secretary general and a past president of the college, Dr James E Paullin Atlanta, Ga, a past president, Mr E R Loveland, executive secretary, Philadelphia, and Col Jack Major, Paducah, Ky At the informal banquet Friday at 7 00 p m Dr William S Middleton, Madison, Wis, president of the college and head of the department of medicine, University of Wisconsin will speak

Broadcast Programs on Democracy in Action—The story of people in a remote mountain valley in Bat Cave, N C, and of young Dr George Bond will be the first of 13 radio programs in a new radio series over the NBC network on Saturday evenings, 7.00-7 30 p m Eastern Standard Time, beginning December 9 The episodes in this series tell the real life stories of how people in various communities in the United States, using democratic methods, acted together to solve their economic and social problems It is produced jointly by the Twentieth Century Fund and the National Broadcasting Company. Other programs in the series deal with democracy in action in the fields of education, labor-management relations, housing, soil conservation and world trade The program employs the recording of on-the-scene voices of the actual persons who lived the story

Environmental Cancer Detection Unit.—A research program aimed to detect materials in everyday life which might be the cause of cancer is being conducted by a Cancer Prevention Committee with international membership and headquarters at the Institute of Industrial Medicine of the New York University-Bellevue Medical Center Announcement of the program was made at a meeting of the Fifth International Cancer Congress in Paris in August The purpose of the committee is to translate laboratory findings concerning environmental causes of cancer into practical application for everyday life in order to prevent persons from coming into contact with agents causing the disease, according to Dr William E Smith, chairman of the committee and a staff member of the Medical Center's Institute of Industrial Medicine The committee includes representatives of university research programs, manufacturers, industrial physicians, engineers industrial and governmental hygienists and statisticians Data concerning certain types of cancer producing materials have already been developed and have been passed on to the industries directly concerned The large insurance companies were particularly cooperative in developing data concerning special cancer hazards

Society Elections—The following officers were elected at the recent meeting of the Association of State and Territorial Health Officers for the fiscal year 1950-1951 Dr Roy L Cleere, Denver, Colorado, president, Dr Leroy E Burney, Indianapolis, vice president, and Dr John D Porterfield III, Columbus, Ohio, secretary-treasurer——The following doctors were elected for the forthcoming year at the November meeting of the American Society of Anesthesiologists, Inc Dr Urban H Eversole, Boston, president, Dr C Walter Metz, Denver, president-elect, Dr J Earl Remlinger Jr, Evanston, Ill, secretary, and Dr. Moses H Krakow, Bronx, N Y, treasurer——At the annual meeting of the National Malaria Society in Savannah, Ga, November 6-10, the following officers were elected for 1951 Justin M Andrews, Sc D, Atlanta, Ga, president, Mr W H W Kimp, Bethesda, Md, president elect Dr Eugene L Bishop, Chattanooga, Tenn, vice president, Samuel W Simmons, Ph D, Savannah, Ga, secretary-treasurer, and George R Coatney, Ph D, Bethesda, Md, editor——At the annual meeting in September of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons Dr James K Quigley, Rochester, N Y, was named president Dr Leroy A Calkins of Kansas City, Kan, is president elect, Dr Herbert E Schmitz, Chicago, vice president, Dr William F Mengert, Dallas, Texas, secretary, and Dr Ward F Seeley of Detroit, treasurer

U. S.-Canadian Allergy Map.—As part of an investigation of allergy, 38 U S and Canadian doctors have completed an allergy map of the two countries, locating the areas of heavy mold spore concentrations Dr Leonard H Harris, Peoria, Ill, headed the committee of the American Academy of Allergy According to the report by this committee, the investigators found two molds, Alternaria and Hormondendrum, in greatest abundance in the Great Plains of the United States, less in the Eastern states and least in the South and Southwest These molds grow in great profusion on wheat, oats, hay and corn Large concentrations of Alternaria, a common cause of some kinds of hay fever and asthma, were found in Chicago, Evanston and Peoria, Ill, Madison, Wis, Indianapolis, Des Moines, Iowa, Oklahoma City, and Ann Arbor, Mich Cities with the lowest Alternaria counts are San Diego and Oakland, Calif, Tucson, Ariz, and Miami Beach, Fla Investigators in the United States and Canadian cities collected daily samples of air-borne molds by dish and glass slide technics Members of the survey committee included Dr Harris, Dr Samuel F Feinberg, Chicago, Dr Theodore B Bernstein, Chicago, Oren C Durham, Ph D, Waukegan, Ill, and Joseph C Gilman, Ph D, Iowa City

National Nursing Improvement Program.—The W K Kellogg Foundation of Battle Creek, Mich, has granted $200,000 to finance a nationwide effort to improve nursing service in hospitals and health agencies during the next three years, under a program being developed by the National Committee for the Improvement of Nursing Services The national committee, with headquarters in New York, will develop plans to help nursing gear its education and service to meet the changing health needs of the nation Factors creating expanded nursing service demands are (1) the changing mode of life from rural to urban, (2) increased use of hospital facilities due to better economy and rapid growth of health insurance plans, (3) expansion of public health programs, (4) increase in employment of nurses in industry, (5) increase in nurses working in doctors' offices, (6) greater participation of nurses in research, (7) delegation to nurses of functions previously carried by doctors and (8) unstable quality and quantity of practical nurses and auxiliary workers

The committee is sponsored by the six national nursing organizations The Joint Commission for the Improvement of the Care of the Patient will serve as an interprofessional advisory committee Committees have been organized in 28 states and two territories The committee has already completed the first step in its program, a nationwide survey of the educational practices in schools of nursing

Medical Television Wins Award—The American Public Relations Association has presented Smith, Kline & French Laboratories Philadelphia, its top award for the year's outstanding public relations project in the use of graphic arts This Silver Anvil Award was given for the firm's project of transmitting surgical and medical procedures to medical meetings throughout the country, using color television Color television was tested in May 1949 at the University of Pennsylvania, Philadelphia This equipment made its debut at the annual session of the American Medical Association in Atlantic City last June In the following year of demonstrations the firm took the equipment 14,000 miles to 11 medical conventions, colorcasting 300 surgical operations and medical clinics to more than 100 000 physicians Included was the first intercity medical colorcast last December during the A M A 's clinical session in Washington, D C, when the program was colorcast from the Johns Hopkins Hospital in Baltimore Other cities visited were Denver, Chicago, New York, Atlanta, St Louis, Boston, Fort Worth and San Francisco, with programs presented to the American College of Surgeons, American Cancer Society, state medical societies of Colorado, Missouri and Texas, the Chicago Medical Society, the Atlanta Graduate Medical Assembly and this year's A M A annual session In the second year of these programs the firm has presented color television to the District of Columbia medical society, Pennsylvania medical society, American College of Surgeons and the International College of Surgeons On the agenda are 13 other meetings

CANADA

Hospital News.—St. Joseph's Hospital, in Montreal, which has been completed at a cost of $5,000,000, will accommodate more than 600 patients. There are a number of special research laboratories and six operating rooms. Two years were required to build the six floor fire-proof hospital.

Mickle Fellowship Awarded.—The 1950 Charles Mickle Fellowship, which is awarded annually by the University of Toronto to "the member of the medical profession who has done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science," has been awarded to Dr. Selman A. Waksman, department of microbiology, Rutgers University, New Brunswick, N. J. The fellowship is accompanied with a cash award of $800, which Dr. Waksman said he will use to further his research in microbiology.

New Medical School Opens in Vancouver.—The Faculty of Medicine, University of British Columbia, commenced its first year of instruction on September 7. The preclinical departments are housed in temporary quarters and clinical teaching will be given at the Vancouver General Hospital and other local hospitals. Instruction during the first year is being offered in anatomy, histology, biochemistry, physiology, history of medical progress, human behavior. introduction to medicine and introduction to public health. Of some 300 applicants, 60 were admitted. Though the minimum academic requirment is three years of college credits after junior matriculation, 52 students have their bachelor's degrees. All but three are residents of the Province of British Columbia. Dr. Myron M. Weaver, dean of the faculty, was formerly assistant dean of the medical sciences, University of Minnesota.

FOREIGN

Mecca Pilgrimage Free of Epidemics.—As a result of international medical and sanitary measures promoted by the World Health Organization (THE JOURNAL, June 17, page 656), the Mecca Pilgrimage of 1950 (Year of the Hegira 1369) was declared "free from infection" and thus cleared of the traditional danger of outbreaks of disease among pilgrims. The Public Health Department of Saudi Arabia has cabled WHO that out of the 500,000 travelers to Mecca, fewer than 120 deaths were recorded. These were caused by sunstroke and general debility of old age; no case of epidemic disease was ascertained.

Maternal and Child Health Center in India.—The World Health Organization and the Indian health services have cooperated in setting up a field center for maternal and child health in a rural area of Delhi Province in India. This project is being enlarged to form an over-all teaching and training project for medical students, nurses and social workers, with courses in Delhi hospitals and colleges also Additional centers in Afghanistan and Burma and other parts of Southeast Asia will help in the improvement of the health of mothers and children and particularly in lowering the infant death rate.

Anti-Rabies Mass Vaccination of Dogs on Mexican Border.—The entire dog population of Ciudad Juarez, Mexico, was recently vaccinated as one of a series of measures to stamp out rabies along the Mexico border. The vaccination of the city's 3,500 dogs was a pilot project conducted by the Mexican health authorities, with the cooperation of the Pan American Sanitary Bureau, Regional Office of the World Health Organization, and will serve as a model for mass vaccination operations in other towns along the border. Aurelio Malaga-Alba, D.V.M., Peru, is coordinator of the rabies eradication program. The National Institute of Hygiene of Mexico City furnished the vaccine, and the equipment and instruments were supplied by the Pan American Sanitary Bureau Public response was prompt. A single veterinarian was able to vaccinate 400 dogs a day, and the entire operation, including humane disposal of all unclaimed dogs that were rounded up in the streets, was completed within eight days. It was reported that last year 179 persons in that city alone received anti-rabies treatment and that from January to September 1950 more than 300 persons had been bitten.

The Pan American Sanitary Bureau was designated in April of 1949 as the coordinating agency for an intensive program of rabies eradication along the U. S.-Mexico border. To standardize the diagnostic procedure throughout Mexico, four laboratory courses were given in Mexico City, which were attended by one hundred physicians, laboratory technicians, veterinarians and bacteriologists. A small group of Mexican scientists came to the U. S. Public Health Laboratories in Atlanta, Ga., to make special studies in rabies diagnosis.

CORRECTION

Costs of Hospitalized Illness.—In the article "Costs of Hospitalized Acute Illness," by Theodore Wiprud and Isidore Altman (Nov. 4, 1950), line 7, second column, page 838, should read "of the hospital bill that Group Hospitalization subscribers."

Fourth General Assembly of World Medical Association.—In the account of the Social Events listed on page 1011 of THE JOURNAL of November 18, the name of E. R. Squibb & Sons was inadvertently omitted from the list of those sponsoring luncheons for the World Medical Association.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written.* July 20. Given simultaneously in several cities in the United States Final date for filing application is Jan. 20 *Oral.* Coronado, Calif., April 4-7 and Memphis, Oct. 14-17. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral, including subspecialties,* Dec. 7-9. Executive Secretary-Treasurer, Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, May 1951. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Part I, Written Examination and Review of Case Histories. Various locations Feb 2, 1951. Final date for filing applications was Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6, Pa.

AMERICAN BOARD OF OPHTHALMOLOGY *Written* Various Centers, Jan 5-6, 1951 *Oral.* San Francisco, March 11-15; New York, May 31-June 5; Chicago, October 8-13. Sec, Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Part II.* Chicago, Jan 25-26. Final date for filing applications was Aug 15, 1950. Final date for receipt of Part I applications for 1951 is Dec. 30, 1950. Sec., Dr. Harold A. Sofield, 122 So Michigan Ave, Chicago 3.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Written.* New York, Jan 8-11, 1951. *Oral.* Richmond, Va., May 1-5. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PEDIATRICS: *Written.* Jan. 19. Under local monitors. Only written examination to be given during 1951. *Oral* New Orleans, March 2-4. Ex. Sec., Dr. John McK Mitchell, 6 Cushman Road, Rosemont, Pa.

AMERICAN BOARD OF PROCTOLOGY: *Part I in Anorectal Surgery and Proctology.* Dallas, Minneapolis, Philadelphia and San Francisco, May 12. Sec.-Gen., Dr. Louis A. Buie, 102-110 Second Ave, S W., Rochester, Minn.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY. New York. Dec 18-19 Final date for filing applications was Sept 1 Sec, Dr Francis J Braceland, 102-110 Second Ave., S W., Rochester, Minn

AMERICAN BOARD OF RADIOLOGY. *Oral* Atlantic City, June 5-9. Sec., Dr. B. R Kirklin, 102 110 Second Ave., S.W., Rochester, Minn

AMERICAN BOARD OF SURGERY: *Written* Various centers, March 1951. Final date for filing applications was Dec. 1, 1950 *Written.* Various centers, Oct. 1951. Final date for filing applications is July 1. Sec., Dr. J. Stewart Rodman, 225 South 15th Street, Philadelphia.

AMERICAN BOARD OF UROLOGY: Chicago, Feb 10 14, 1951 Final date for filing applications was Sept. 1, 1950. Chicago, Feb 9 13, 1952. Final date for filing applications is Sept 1. Sec., Dr. Harry Culver, 314 Corn Exchange Bldg, Minneapolis 15.

Coming Medical Meetings

American Medical Association, Clinical Session, Cleveland, Dec. 5-8. Dr. George F. Lull, 535 N. Dearborn St, Chicago 10, Secretary.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 2-7. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland, Secretary.

American Association of Medical Clinics, Hotel Cleveland, Cleveland, Dec. 4. Dr. Arthur H. Griep, Welborn Clinic, Evansville, Ind, Secretary.

American Psychoanalytic Association, Waldorf-Astoria Hotel, New York, Dec. 7-10. Dr. LeRoy M. A. Maeder, 1910 Rittenhouse Square, Philadelphia 3, Secretary.

American Society for Surgery of the Hand, Palmer House, Chicago, Jan. 26 Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

International Post Graduate Medical Assembly of Southwest Texas, Municipal Auditorium, San Antonio, Jan. 23-25. Dr. John H. Hinchey, P. O. Box 2445, San Antonio 6, Secretary

Puerto Rico, Medical Association of, Santurce, Dec. 13-17. Dr. Victor J Montilla, P. O Box 3866, Santurce 29, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 10-15 Dr. Donald S. Childs, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

Southern Surgical Association, Hollywood Beach Hotel, Hollywood, Fla., Dec. 5 7. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

DEATHS

Halliday, Charles H., Baltimore; born in Metropolis, Ill., Sept. 26, 1880; College of Physicians and Surgeons, Baltimore, 1904; medical officer, United States Coast and Geodetic Survey, 1905-1906, when he joined the medical department of the U. S. Army in the Philippines and resigned in 1915 to accept position as medical superintendent of Zamboanga Hospital in the Philippines; a year later joined the Royal Army Medical Corps and served in France until November 1917; rejoined the American Army as captain and was assigned to Military Hospital in Paris from November 1917 to April 1918; medical inspector, Chateau Thierry Sector, April 1918 to October 1918; promoted to major in 1918; at the request of the International Red Cross Society he became epidemiologist for the Ministry of Health of Poland and then served with the American-Polish Typhus Commission from August 1919 to December 1919; later was medical inspector for the American Red Cross Commission to Poland, then deputy commissioner to Poland; senior epidemiologist for the Minnesota State Department of Health in 1921; surgeon in the U. S Public Health Service Reserve, 1921-1922, when he was appointed epidemiologist for the California State Department of Health; in 1929 accepted position as epidemiologist for the Maryland State Department of Health and was later made chief, bureau of communicable diseases, serving in this capacity until his retirement in January 1950; colonel in the Maryland State Guard during World War II; received decorations from the United States, Britain, France, Poland and Russia; died in the University Hospital September 30, aged 70, following a gallbladder operation.

Allen, Elijah Henry, Washington, D. C.; Howard University College of Medicine, Washington, 1894; for many years affiliated with Freedmen's Hospital, where he died September 28, aged 89.

Baker, Archie Maurice ⊕ Lindenhurst, N. Y.; Syracuse University College of Medicine, 1922; member of the American Association of Industrial Physicians and Surgeons; past president of the Suffolk County Medical Society; served as village health officer; member of the board of education; director of the Lindenhurst Bank; affiliated with Southside Hopital, Bay Shore; consultant at Kings Park (N. Y.) State Hospital; died September 24, aged 54. of acute myocardial infarction

Baker, Frank Macklin ⊕ Indianapolis; Northwestern University Medical School, Chicago, 1936; served during World War II; affiliated with the Veterans Administration Hospital at Fort Harrison, where he died September 24, aged 40, of myocardial infarction.

Balliet, Tilghman M., Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1887; professor of therapeutics, emeritus, Dartmouth Medical School, Hanover, N. H.; died September 27, aged 91.

Belknap, Virgil Clarence, Nampa, Idaho; Jefferson Medical College of Philadelphia, 1894; member of the American Medical Association; affiliated with the State School and Colony; on the staff of Mercy and Samaritan hospitals; died September 20, aged 78, of coronary thrombosis.

Benson, Gideon H., ⊕ Richland Center, Wis.; Rush Medical College, Chicago, 1904; served during World War I; president of the board of education and coroner; director of the Farmers and Merchants Bank; died in Presbyterian Hospital, Chicago, September 26, aged 83, of bronchopneumonia.

Berry, Jerome Francis ⊕ Kalamazoo, Mich.; University of Vermont College of Medicine, Burlington, 1913; in 1937 was appointed to what was then the newly created Michigan State Hospital Commission; served during World War I; for many years affiliated with Kalamazoo State Hospital; died in the New England Deaconess Hospital, Boston, September 23, aged 64, of gastrointestinal hemorrhage.

Carolus, Walter I., Sterling, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1902; member of the American Medical Association; served as city health officer; died in Community General Hospital September 18, aged 77, of carcinoma.

Diedling, Rudolph Francis, West Palm Beach, Fla.; Albany (N. Y.) Medical College, 1896; served during World War I; died September 14, aged 75, of heart disease.

Ewing, John Sharp ⊕ Newellton, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1904; served during World War I; died in Vicksburg, Miss., September 18, aged 70, of carcinoma of colon.

Heim, Lyman David ⊕ Schuylkill Haven, Pa.; Jefferson Medical College of Philadelphia, 1903; for many years president of the board of health of Schuylkill Haven and member of the board of education; past president of Schuylkill County Medical Society; one of the founders and served as chief of staff of the A. C. Milliken Hospital in Pottsville and the Good Samaritan Hospital; physician for the county almshouse; died September 19, aged 73, of heart disease.

Janson, Christian William, Brooklyn; Cornell University Medical College, New York, 1902; fellow of the American College of Physicians; member of the National Gastroenterological Association; served with Wyckoff Heights Hospital and Lenox Hill Hospital; died September 15, aged 71, of coronary thrombosis.

Keppel, Frederick Dudley, Syracuse, N. Y.; Southern Homeopathic Medical College, Baltimore, 1897; served during World War I; surgeon of the Army and Navy Union of New York State; died September 13, aged 77, of coronary occlusion with infarction.

Lynch, Thomas Augustine, Lowville, N. Y.; Fordham University School of Medicine, New York, 1919; member of the American Medical Association; served during World War I; served as physician for Lowville Free Academy, the Lewis County Jail, and Lewis County Selective Service Board and health officer of the village of Lowville; affiliated with Lewis County General Hospital, where he died September 17, aged 54, of injuries received in a fall.

Maben, Buel Wilber, Kingston, N. Y.; Long Island College Hospital, Brooklyn, 1892; died in the Masonic Home Hospital, Utica, September 15, aged 80, of coronary sclerosis.

McCall, Samuel W., Collierville, Tenn.; Memphis (Tenn.) Hospital Medical College, 1893; died September 18, aged 82, of cerebral hemorrhage.

Meinzer, Martin Stoetzel ⊕ Perth Amboy, N. J.; Columbia University College of Physicians and Surgeons, New York, 1905; fellow of the American College of Surgeons; formerly school physician, city physician and on the board of health; served on the staff of Perth Amboy General Hospital, where he died September 14, aged 72, of acute myocardial infarction.

Parker, Paul Godwin ⊕ Erwin, N. C.; Medical College of Virginia, Richmond, 1916; member of the board of medical examiners of the State of North Carolina; past president of the Harnett County Medical Society; served during World War I; president of the county board of health; affiliated with Good Hope Hospital; died September 19, aged 57, of coronary occlusion.

Pearson, Charles Edward, Staten Island, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1900; member of the American Medical Association; fellow of the American College of Surgeons; past president of the Richmond County Medical Society; at one time trustee of the Staten Island Savings Bank; formerly served on the staff of Seaview Hospital; for many years affiliated in various capacities with Staten Island Hospital, where he died September 16, aged 72.

Sauthoff, August ⊕ Madison, Wis.; Rush Medical College, Chicago, 1905; member of the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology; served on the staff of the Mendota State Hospital; died September 19, aged 74, of subdural hematoma and cerebral contusion as the result of an automobile accident.

Scouler, Ambrose Alphonse, New York; Columbia University College of Physicians and Surgeons, New York, 1896; for many years in charge of the tuberculosis clinic of the health department in Brooklyn; affiliated with St. Vincent's Hospital; died in Fair Oaks Sanatorium in Summit, N. J., September 18, aged 78, of arteriosclerosis and cardiac asthma.

Seitz, George, Holyrood, Kan.; University Medical College of Kansas City, Mo., 1900; member of the American Medical Association; served as health officer of Saline County; died in St. John's Hospital, Salina, September 14, aged 71, of cerebral hemorrhage.

Smith, Frank Campbell, Bessemer, Ala.; Birmingham Medical College, 1903; member of the American Medical Association; affiliated with the Employees Hospital of Tennessee Coal, Iron and Railroad Company in Fairfield, where he died in the Lloyd Noland Hospital September 14, aged 71, of myocardial infarction and coronary disease.

⊕ Indicates Fellow of the American Medical Association.

FOREIGN LETTERS

LONDON

(From a Regular Correspondent)

Sept. 22, 1950.

International Society of Haemotology

The Third Congress of the International Society of Haemotology was held in Cambridge, under the presidency of Sir Lionel Whitby, August 21-26.

Anemia.—The first meeting on this subject was devoted to therapy, and Dr. E. Lester Smith (England) opened with a paper describing the isolation and properties of vitamin B_{12}. This was followed by a discussion by Dr. E. H. Morgan and his co-workers (United States) and Dr. Grace Goldsmith (United States) on the effect of the oral administration of vitamin B_{12} *in pernicious anemia, in the absence of known sources of the* intrinsic factor. The latter described the effects of vitamin B_{12}, given orally and parenterally. Other contributions concerned the therapeutic effect of vitamin B_{12} obtained from a variety of new sources, the use of the vitamin in the treatment of tropical macrocytic anemia and the effect of cobalt therapy in various anemias. Dr. O. P. Jones (United States) described the action of antianemic substances on embryonic prehepatic erythropoiesis. Dr. G. Larsen (Norway) described the pathogenesis of the macrocyte and pointed out that even in adequately treated pernicious anemia macrocytes still showed in the peripheral blood. The thickness of the cells was about half of normal and their life span 40 to 60 days. Further papers and discussions centered on whether vitamin B_{12} alone was an adequate hemotherapeutic agent in pernicious anemia.

On August 25 a session was devoted to nutritional factors in anemia, and Dr. C. R. Das Gupta (India) discussed the etiology of nutritional macrocytic anemia. Drs. V. Ramalingaswami and H. M. Sinclair (England) spoke on the etiology and pathogenesis of polycythemia in pyridoxine deficiency in the rat. Dr. J. F. Rinehart (United States) gave an account of experimental pyridoxine deficiency in the rhesus monkey. The action of folic acid, liver extracts, vitamin B_{12} and other substances with antianemic properties as described by Dr. A. Aschkenasy (France), L. Tentori and G. Vivaldi (Italy), O. Carrere-Comes (Italy) and G. Sotgiu and C. Cacci (Italy). Dr. A. R. Axelrod and L. Berman (United States) presented their findings in the bone marrow in hypothyroidism and hyperthyroidism. The incidence of lymphocytes in bone marrow in hyperthyroidism may reach levels comparable to chronic lymphatic leukemia with no peripheral lymphocytosis.

Leukemia.—Leukemia due to benzine, one of the rare human leukemias of which the cause is known, was the subject of papers by Dr. J. Bernard (France) and Dr. L. Braier (Argentina). The cytology of acute leukemias, unusual types of leukemias in children, the possibility of a virus in the etiology with some supporting experimental work and the significance of leukemia plasma in cytogeneses were also discussed.

Problems of Coagulation.—The session here was opened by Dr. F. J. Leibetseder (Austria) who discussed the effect of epinephrine and dihydroergotamine on the first stage of coagulation. Drs. R. Breda and R. Bernardi (Italy) described a condition present in two brothers belonging to a family affected with hereditary hemorrhagic telangiectasia, who showed a prolongation of prothrombin time. Experiments conducted with plasma from these cases suggested the possibility of an antiprothrombin conversion factor. Other experts described the coumarin treatment of experimental thrombosis. The correlation between deficiencies or increases of blood-clotting factors and dysproteinemias was described by Dr. P. de Nicola (Italy). The clinical and hematological problem of thrombophilia was discussed.

Immunohematology.—In the first meeting devoted to immunology, papers were read by Dr. L. Berman and co-workers (United States) on the so-called lupus erythematosus inclusion phenomenon. The present position of blood groups was reviewed briefly by Dr. J. Van Loghem (Holland). An account was also given by other experts on the Duffy blood group system. Dr. A. D. Mourant (England) described the distribution of blood groups in relation to transfusion organization, and Dr. G. Fulton Roberts (England) discussed the prozone inhibition that some antiglobulin serums show when tested against weakly sensitized cells.

Dr. A. S. Wiener (United States) described with illustrative cases the medicolegal application of the rhesus blood types. Dr. P. Levine (United States) summarized the position of the Kell-cellano system of blood factors, and Drs. R. R. Race and R. Sanger (England) described a blood lacking in any detectable representative of the C and E series of allelomorphic antigens. This case represents a probable deletion in a human Rh chromosome and supports the separability of the C, E and D genes. A notable paper was presented by Dr. S. Filitt-Wurmser and co-workers (France) on the differentiation of "A" blood groups by their agglutinins. Dr. P. Vogel (United States) helped to conclude the session by a communication on the technical consideration and results in replacement transfusion in infants.

The Clerical Work of a Doctor's Surgery

A recent report by Dr. E. D. Willis and Anne G. Shaw in the *British Medical Journal* on the clerical work in a physician's surgery aroused sufficient interest to appear summarized in the *London Times.* With the increase of clerical work, e. g., compulsory record keeping and certificate writing involved in the change-over in this particular practice, from one that was mainly "private" to one mainly "national health," the services of a motion study investigator were enlisted to eliminate redundancy and improve the efficiency of the record keeping of the practice.

A definition of motion study is given in the article as the scientific investigation of the movements involved in the performance of any piece of work and the development of a plan which eliminates unnecessary movement and conserves energy, time and material. This method of improving efficiency is, of course, well known in industry. The first essential in such an investigation is a study of existing methods, then to record them and analyze them and then to make use of one of the available technics to institute improvements. In this case a simple technic sufficed, that is, the process chart. This chart makes available a series of facts in such a way that they can be both visualized as a whole and examined in detail. The process chart enables each detail of procedure to be questioned. Is its place in the sequence right? Can it be combined with any other detail? Can it be simplified? On this a further chart is made and a new simplified and streamlined procedure is evolved, and, it seems to have been a definite improvement in the clerical work both as regards efficiency and the volume handled.

In examining the clerical procedures in the practice, the investigators found there were three sets of records: a log book, into which messages received by telephone were entered immediately; a visit book, in which records were kept, month by month, of patients visited in the course of an illness, and a record of the necessity of visiting a chronically ill patient, that is, a routine follow-up visit. Third, a series of record cards for private and national health patients on which clinical details were noted and, in the case of the former, the fee was recorded.

In the new methods evolved, the investigator was able to eliminate the second record, the visit book, entirely. He did this by making further use of the permanent record cards and by making space available for a wall rack into which each morning the secretary placed cards for the patients being treated, the chronically ill patients due for a visit and any new patients' cards which may have come in from the previous day (telephone requests or visits). The cards were arranged in columns for each day of the week. Space was made available at the end of the rack for two columns for cards which were required during the following two weeks.

A small sliding table was placed at the bottom of the wall rack containing prescription forms, certificate forms and the National Health Formulary, so that when the doctor returned from a visit he could write out notes, prescriptions and certificates on the spot. He could also enter details on cards where needed and regroup the cards where necessary. The laborious copying of the names of patients who were visited in one month into the page for the new month was thus eliminated. Instead of having to go both to the log book and to the visitors book when compiling the list of visits for the day, the doctor merely had to glance at the cards in the column for a particular day and make a list in his notebook of the patients who required a visit. On the return from the visit notes from the notebook were entered on the card. As a result of this the doctor is able to perform necessary clerical work more efficiently and the greater volume due to the National Health Service and have more time for the clinical examination of patients, and perhaps more time for well earned leisure.

Colchicine in the Chemotherapy of Cancer

No doubt stimulated by the recent reports on the so-called secret cure for cancer, and by its leading article on the subject, the *British Medical Journal* in another leading article published an interesting review of the therapeutic effect of colchicine in cancer. In the first article it was pointed out that part of the secret cure was suspected of being oral administration of colchicine. The drug, they say, is a radiomimetic and has been much used in research for a chemotherapeutic agent against cancer. It is an alkaloid derived from the autumn crocus and is probably the most powerful "radiomimetic" drug known; the cellular changes induced are similar to those induced by roentgen rays. Even at dilutions of 1 to 100,000,000 it can bring about the typical mitotic arrest at the metaphase stage. Microscopically, areas of a tissue treated with colchicine will sometimes show more cells in arrested division than in the resting state. Ludford (*J. Nat. Cancer Inst.* 6: 89, 1945) examined the mode of action of colchicine on tissues grown in vitro and observed that the drug does not differentiate between embryonic and neoplastic tissues, which are equally sensitive to its mitosis-arresting activity. Although other drugs produce a similar effect, Ludford points out that colchicine is unique, in that it does not arrest the initial phase of division but brings the process to a standstill at the metaphase in a remarkably wide range of concentrations. There is little evidence that it stimulates mitosis as well as block it at the metaphase. Further evidence shows that in high dilution it slows down the rate at which cells enter the mitotic cycle. Macroscopically, the most obvious effect of the drug on a tumor is hemorrhage of the kind also caused by polysaccharide fractions of bacterial filtrates, for instance, from Serratia marcescens. Although there is a close parallel between the nucleotoxic action of colchicine and of roentgen rays, e. g., the acquired tolerance of tumor cells to the drug and the acquired radio resistance of tumors which were previously radiosensitive, the article points out there are certain differences in the toxic effects on the nuclear chromatin. Colchicine is much more specific in its action on the nuclear structures. Probably the most outstanding difficulties in the colchicine treatment of tumors is the lack of cell type specificity. Tests with the aim of supplementing the action of colchicine with radiotherapy have been, on the whole, without success. Several workers have investigated the action of colchicine in the treatment of cancer in man, but it was found that the drug caused very unpleasant symptoms, and sometimes death from colchicine poisoning. A woman with adenomedullary carcinoma of the breast was treated with colchicine combined with roentgen rays. The lesion shrank to a third of its original size and then began to grow again rapidly, with fatal results. In a patient with an anaplastic carcinoma of the neck a similar reaction was noted; the central portion of the tumor became necrotic, but the peripheral layers grew with increasing speed. The article sums up by citing Seed, Slaughter and Limarzi to the effect that, although the rapidly growing cancer cells are much more susceptible to the poison, the concomitant general toxic effect is much too great to permit any curative effect.

Gastrectomy

In a leading article, the *Lancet* produces some interesting figures with regard to gastrectomies. It states that it would probably be fair to say that 95 per cent of patients survive the operation, 75 per cent are relieved of their old symptoms without acquiring new ones and 20 per cent have further symptoms due either to recurrent ulceration (3 to 4 per cent) or to disturbance of alimentary function. This disturbance, they state, is occasionally severe. They quote one doctor-contributor, "If he had known about the attacks of extreme lassitude which were to follow his gastrectomy he would rather have kept his ulcer and borne its pain."

FLORENCE, Sept. 17, 1950.

Protein Synthesis

In addition to the lectures presented at the Superior Institute of Public Health in Rome which were previously reported, Prof. Artturi Virtanen, Nobel Laureate and director of the Institute of Biochemistry in Helsinki, spoke on nitrogen assimilation and protein synthesis. While most micro-organisms and higher plants use as a source of nitrogen either nitrates or ammonia, some micro-organisms are able to use molecular nitrogen. According to the speaker, the metabolic pathways which start from these sources of nitrogen must converge at an early stage, because there is no appreciable difference in the proteins or in the enzyme systems of the cells, irrespective of the source of the nitrogen. The role of ammonia in the synthesis of the amino acids has been amply confirmed, but hydroxylamine originating through reduction of nitrates and the aerobic fixation of molecular nitrogen may also take part in the synthesis of the amino acids.

The speaker discussed also the formation of the peptide linkage and the synthesis of protein. Whether amino acid synthesis precedes the formation of the peptide linkage or whether the amination occurs after the linkage is formed is not known. The concept of Bergman on the enzymatic formation of peptides through a dehydration process is not universally accepted and, from the point of view of energy requirement, does not seem likely. On the other hand, the participation of a phosphoric acid ester in the synthesis seems well founded. The synthesis of polypeptides, considered as counteraction to enzymatic hydrolysis, has been studied recently by the speaker and his co-workers. The peptides, having a small molecule, combine to form under the action of pepsin a polypeptide, with a larger molecule, the synthesis of which proceeds gradually. At the beginning, polypeptides of an average of 8 to 12 peptides of small molecule are formed. With longer periods of reaction, the size of the polypeptides increases continuously; the average molecular weight of the largest synthesized polypeptides is about 12,000. The roentgen diffraction pattern of such polypeptides is similar to native protein, but the rings are clearer and more defined. The potential energy for the synthesis of polypeptides by the action of proteases seems to be greater than the energy required for the synthesis of dipeptides and tripeptides. The synthesis of polypeptides (plasteins) has been obtained from zein hydrolysate by the action of pepsin. The great specificity of proteases and their behavior in the in vitro synthesis of polypeptide chains prove synthesis of polypeptides in vivo under the influence of proteases.

COLOMBIA

(From a Regular Correspondent)

BOGOTÁ, Sept. 15, 1950.

Basic Principles for a Public Health Program

The economic mission organized by the International Bank for Reconstruction and Development in Washington, under the auspices of the Colombian government, formulated a program to raise the standard of living in Colombia. The mission presented its report to the authorities in Washington and in Bogotá on August 13. This plan achieves one of the main purposes of the institution, namely, to give advice and technical aid to countries. The mission, presided over by Mr. Lauchlin Currie, worked in Colombia for one year. The results accomplished were recently reported in a 900 page book, "Principles of a Program for the Improvement of Public Health and Standards of Living in Colombia," published by the Press of the Bank of Colombia. The program planned will be developed in the course of five years. It covers the fields of industry, agriculture, public roads, oil wells, electric power, public works, taxes, international exchange and public hygiene. The program is now under careful study by the heads of the International Bank for Reconstruction and Development and by the government of Colombia. The chapter concerning hygiene and public health contains the following statement: "Health is the most important factor in raising the standard of living of the people." The life expectancy at birth in Colombia is less than 40 years, whereas in countries with good sanitary conditions it is 70 years. This reduced life span together with early deterioration of working capacity of laborers, because of poor health, causes a higher proportion of dependents for each worker, more than 4 to 1.. The incidence of diseases, including endemic tropical diseases as well as those common to temperate zones, is high. Nutritional disorders are common. The sanitary precautions are minimal. Purification of milk and the sewer and waste disposal systems are inadequate. These problems are receiving attention. The campaigns against malaria and other common diseases in the country have begun Several hospitals and medical centers have been built, and an extensive program for the construction of aqueducts and sewers has been started. However, there is still a great deal to be done.

The most important aspect of a public health program lies in the prevention of disease. The following needs call for prompt attention: (1) organization of the public health service with definition of its functions, (2) protection of the health of the people by the supply and maintenance of sanitary facilities, (3) recruitment and training of professional personnel for public health service and (4) enlargement and improvement of hospitals and other medical centers.

The mission recommends that the relations between the Ministry of Hygiene and the dependent agencies be clarified. The national government should continue to give financial support to the local dependent agencies. The Ministry of Hygiene should supervise the distribution and use of such funds and should otherwise restrict itself to functions such as preparing and issuing laws, fixing standards of health, giving advice and collecting data from research work and statistical studies. It should be responsible for the administration of certain health and hygiene institutions of the entire country or of the large regions of the country. The departments under the ministry should be responsible for services such as the organization and function of clinics for the diagnosis of disease and the distribution of drugs and biological products; the municipal dependencies would carry on most of the routine treatments and the activities for prevention of diseases in the municipalities. The main requirements are housing, adequate public services, aqueducts, sewers, hygienic toilets and septic tanks. Measures for controlling sanitation and the quality of foods and milk are important.

It is calculated that 2,750 physicians, 870 dentists and dental assistants and 6,250 nurses will be needed in 1955 to carry out the program. This increase over the present figures for the aforementioned categories is considerable. For this reason, public employment of physicians and persons in the medical branches, mainly on a part time basis, will be necessary. Several measures, such as the creation of the National School of Hygiene, have been taken to increase the reserves of personnel. The mission recommends a substantial increase in salaries, better working conditions, security of jobs and opportunities for progress by means of a genuine merit system. Emphasis is given in the report to the campaign against infectious and parasitic diseases. The progress obtained in recent years in the treatment of such diseases as malaria, smallpox, diphtheria, whooping cough, syphilis and gonorrhea has been so satisfactory that these campaigns, if properly organized, would have excellent results. It is recommended that the present program against leprosy, which now uses up almost one fourth of the national budget for hygiene, should be modified. The actual expenses are excessive in proportion to the importance of leprosy in Colombia.

The Ministry of Hygiene calculated hospital needs on the basis of 5.3 beds per 1,000 persons (the present proportion is 2 per 1,000). This expansion seems to be too great to be accomplished in five years. It is therefore suggested that hospital beds be increased in a proportion of 3 beds per 1,000 persons for the whole country. The minimum proportion will be 2 per 1,000. This program requires more than 17,000 new beds in the general hospitals. The provision of 4,500 additional beds for tuberculosis is recommended. The Ministry plans to build some 146 health centers in the large cities and 648 subordinate centers in the small towns.

The most important social welfare centers are the Social Welfare and Public Aid stations. These centers are supported and supervised by the national government, and their activities are limited almost exclusively to the support and administration of hospitals and other institutions. A much greater number of workers is needed. The annual cost of the program will be about 24 per cent of the total budget—8 per cent for health and maternity, 4 per cent for a pension plan, 4 per cent for invalidism, 4 per cent for old age benefits and 4 per cent for workers' insurance. The employer, the employee and the government share equal portions in the premium. The problem of the relations between the social security system and the other programs of hygiene and social welfare is complicated. The mission did not intend to reach definite conclusions. However, it points out that the new program of social insurance should be developed without interfence with the progress of previously organized social services.

Personals

Dr. Braulio Henao Mejia, former dean of the school of medicine of the University of Antioquia and professor of the gynecology clinic, was appointed governor of the District of Antioquia.

Dr. Gonzalo Montes Duque, professor of pharmacology at the National University and former public official of UNRRA, was named secretary of social aid of the Department of Cundinamarca.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Osteopathy: Osteopath's Right to Practice Surgery and Use Drugs.

This was an action to restrain the Governor and Attorney General of Kansas from enforcing the medical and osteopathic practice acts as construed by the Kansas Supreme Court. The hearing was held before a three judge court in the United States district court, district of Kansas, second division.

The plaintiffs, osteopaths licensed under the laws of Kansas, claimed that the Kansas medical and osteopathic practice acts as interpreted by the Kansas Supreme Court are void and in violation of the Fourteenth Amendment of the Constitution of the United States for the reason that such interpretations have prohibited the plaintiffs from using drugs and operative surgery in their practice of osteopathy notwithstanding that in osteopathic schools they are required to study and qualify themselves in the use of drugs and the practice of surgery. This, they said, deprives them of liberty and property without due process of law.

The Kansas Supreme Court has, on several occasions, interpreted the applicable statutes to mean that persons licensed to practice medicine and surgery may use drugs and surgery, while those licensed to practice osteopathy are prohibited from practicing medicine and surgery. Under this construction, certain of the plaintiffs had been personally enjoined from the use of drugs and surgery. The plaintiffs, both by evidence and argument, pointed to their educational qualifications, to the standard of osteopathic colleges generally, to the training received by osteopaths in comparison to that of doctors of medicine and surgery and to the scope of the examination given osteopaths by the state osteopathic board. They asserted that they study the use of drugs and the performance of surgery in their schools to the same extent that medical students do in medical schools and that on graduation they are qualified in these branches of the healing art to the same extent as are graduates from medical schools. They therefore contended that the restrictions placed on them are unreasonable, arbitrary, detrimental to the public health, an unreasonable exercise of the police power, discriminatory and in violation of the Fourteenth Amendment of the United States Constitution.

The court found that as of 1913 (the year in which the osteopathic act was passed) the course of study in osteopathic schools did not include the study of materia medica and pharmacology, that in other respects the course of study in osteopathic schools with regard to the use of drugs and performance of surgery was substantially the same as in medical schools, the pedagogy differing only in emphasis, intensity and degree. It is well settled, said the court, that the police power of the state extends to the regulation of certain trades and callings, particularly those which closely concern the public health. Practitioners of the healing art are properly subject to police regulations, the details of which are primarily with the legislature and are not to be interfered with by federal courts so long as fundamental constitutional rights are not violated. Equal protection of the laws does not preclude states from resorting to classification for various purposes of legislation, and narrow distinctions will justify classification in legislation if they are reasonably related to the objects of legislation. In pursuance of this power, the court continued, Kansas has seen fit to differentiate between the treatment of human ills through the use of drugs and surgery and the treatment of such ills by means of manipulative therapy. In regulating the practice of the two branches of the healing art, different educational requirements are made for each. The examinations given to applicants of each class are distinguishable under the pertinent statutes designed to insure qualified, licensed practitioners in each of the two fields. Kansas has seen fit to set up one board to examine those who would practice surgery and the use of drugs and a separate board to examine those who would practice cure of disease by manipulation or osteopathic practices. It has set up the qualifications which applicants must meet who would take the examination before the medical board for the right to practice surgery and medicine and the qualifications of applicants who would take the examination before the osteopathic board for the right to practice osteopathy. No one would seriously contend that it is arbitrary or unreasonable to compel one who seeks the right to perform surgery or administer drugs and medicines to be a graduate of an approved school or that he take the examination before a board composed of members qualified specially in such subjects. In order for plaintiffs to make a case entitling them to relief under the Fourteenth Amendment, the court continued, it is necessary for them to show that the osteopathic colleges from which they are graduates meet all the educational requirements of the Kansas statutes and of the rules adopted by the medical board for those who would practice surgery and the use of drugs and medicine, that they are approved schools, or that approval has been arbitrarily and unreasonably denied, and that they have been denied the right to take the examination before the medical board. The plaintiffs contended that graduating from osteopathic colleges maintaining comparable courses of study with medical schools and passing the osteopathic board of examination are sufficient to entitle one to the practice of medicine and surgery. With this contention the court did not agree. It is still necessary, said the court, that such schools be approved as provided by law and the appropriate regulations and that graduates therefrom take the examinations before the medical board. Of course, if approval were arbitrarily denied to a qualified osteopathic school and if its graduates were arbitrarily denied the right to take the examination before the medical board, a different question might arise, but such is not the case here. Statutory regulations requiring all applicants for the right to practice surgery and the administration of drugs and medicine to be graduates of approved schools and to take an examination before a medical board composed of members qualified in such subjects are not unreasonable or arbitrary and therefore do not contravene any rights provided by the Fourteenth Amendment.

In a supplemental opinion, after reviewing a number of cases and statements from college catalogs, the court said that osteopathy wholly repudiates drug therapy and sanctions the use of drugs only as anesthetics, external antiseptics, antidotes for poison and possibly as a palliative for pain. Furthermore, osteopathy recognizes that surgery should be employed, when necessary, not as a part of the practice of osteopathy, but as a complement thereto. These catalogs state in substance that the practice of osteopathy and major surgery should not be combined; that the school undertakes to prepare its students to do minor surgery only, to diagnose conditions in cases when major surgery should be resorted to and to give after-treatment in major surgery cases. Such catalogs further state in substance that, while the teaching of surgery has been broadened to meet the demands of patients, osteopathy would never countenance the use of drugs except for the limited purposes stated above. Thus it will be seen, the court continued, that in the year 1913 there were fundamental differences in the osteopathic theory of therapeutics and the practice of osteopathy and the theory of therapeutics of medicine and surgery and the practice of medicine thereof. These fundamental differences fully justified the state in placing the practice of osteopathy in one classification and the practice of medicine and surgery in another classification, in establishing different educational requirements and providing different examinational tests for osteopaths and in restricting osteopaths to the practice of osteopathy, in order to preserve the public health and welfare. It may be that the curricula of the schools of osteopathy have either been broadened or varied since 1913 so as to teach a limited use of drug therapy and so as to better prepare their students for the performance of surgery as a complement to the practice of osteopathy. Osteopathy, however, was a system of treating diseases of the human body without drugs or surgery and colleges cannot change the laws of Kansas or widen the scope of the osteopath's certificate so as to permit him to practice other systems of healing by the simple expedient of varying their curricula. If an osteopath in Kansas desires to engage in the practice of medicine and surgery, he must meet the requirements laid down for a license so to do. These requirements are attainable by reasonable study and application, are appropriate to the end sought to be attained and are neither unreasonable nor arbitrary. If the osteopathic colleges desire to broaden or vary their curricula so as to train their students not only to practice osteopathy but medicine and surgery, they must meet the requirements to constitute them approved medical schools. Accordingly the injunction requested by the plaintiffs was denied and judgment was entered in favor of the defendants. —*Gleason v. Carlson, 92 F Supp. 280 (Kansas 1948).*[1]

Medical Motion Pictures

The following 16 mm., black and white, sound films are the entire Marriage Series, consisting of five motion pictures produced in 1950 by Affiliated Film Producers for the McGraw-Hill Book Company. They have been planned to complement a textbook, "Marriage for Moderns," prepared by Dr. Henry Bowman, Chairman, Division of Home and Family and Department of Marriage Education at Stephens College, Columbia, Mo. Procurable on purchase from McGraw-Hill Book Company, Inc., Text-Film Department, 330 West Forty-Second Street, New York 18, and on rental from Association Films, Inc., 35 West Forty-Fifth Street, New York 19, or the regional office.

This Charming Couple. Showing time 19 minutes.

This film deals with the reasons why many marriages fail even though both partners are decent, well meaning persons. In the film, the hero and heroine each try to make over the other, instead of accepting each other as human beings with certain strengths and weaknesses that cannot be greatly altered. The situations which are portrayed could each have been worked out with a reasonable degree of satisfaction, had the two young persons been realistic, instead of romantically insisting on a "dream boy" or "dream girl."

This production would elicit stimulating discussion in any young people's group. While the setting is a college campus, groups of young men and women who have not attended college could identify themselves with the human characters shown. Guidance personnel or leaders of young people's groups would also find the film valuable. Skilled leadership for discussion following the film would be necessary, for there are some situations which might be threatening to young people unless they were discussed afterward.

Marriage Today. Showing time 22 minutes

This motion picture illustrates how two young couples have worked out some of the problems of marriage by being more generous and accepting of one another than the unfortunate pair in "This Charming Couple" were able to be. In both couples, the relationship is always more important than the momentary satisfaction of the individual. Realistic situations, in which one partner cheerfully gives up what he or she wants at the moment to cooperate with and support the other, drive home the lesson of "Marriage Today" vividly and sympathetically.

Unlike the other films of this series, it makes use of a narrator rather than of the conversation between the characters to make its points. The result is that this film tends to become "preachy" in spots. It would probably not hold the attention of a group of young people as well as some of the others in the series. However, the positive encouraging approach of the film is so good that it outweighs any shortcomings it may have.

The film would be useful with college age people, young married couples or for guidance personnel in training. Young people could identify with the real life situations and feel better able to cope with their problems as a result. Discussion under skilled leadership would help young people clarify their ideas about the situations portrayed, but discussion might not be as spirited as with some of the other films.

Choosing for Happiness. Showing time 14 minutes.

Through the conversation and behavior of two girls on a college campus, two different ways of dealing with the opposite sex and choosing a mate are portrayed. Without being at all moralistic in tone, the film shows how the girl who always wants to change her men "for their own good," or who wants someone perfect, is sure to be disappointed. The girl who is somewhat less attractive but more accepting of people does better in the long run. This girl is able to help her more demanding friend see that she must be willing to adjust if she is to find happiness.

This film brings in many kinds of young people, the athlete, the "brain," the quiet one and the strong-willed one. It holds one's interest and is perhaps the most effective of the series, for it is neither a "success story," like "Marriage Today," nor is it in any way threatening, as "This Charming Couple" might possibly be.

Young people from the junior year in high school through college age would enjoy and profit by this film. It would be of value for parents of older adolescents or for teachers and guidance personnel. Discussion following the showing of this film should be provocative and lively. Like the others in this series, it could well stand alone; it would appeal to a wider age group then almost any of the others.

It Takes All Kinds. Showing time 20 minutes.

This film portrays, in a series of young people, the humorous and kindly reaction of different kinds of personalities in a tense situation. Each type of personality is shown with a member of the opposite sex, and his or her characteristic way of meeting situations is portrayed in terms of what he or she says and does on a date. The point of the picture is that in order to make a happy marriage, the partners do not have to be alike but must accept each other as they are.

The narration and conversation are skilfully combined in this film to make the different reactions of individuals, when the car runs out of gas, seem intensely human and distinctly different from each other. The author of the film has shown the strengths and weaknesses of each type so that one is left with the feeling that successful persons must all behave alike. The only possible criticism might be that somewhere in the film the statement could have been made that one does not always react in the same way to similar events, and that we all have some slight mixture of many different types of behavior. The need for even the most independent to be occasionally dependent or for the dependent to become dictatorial on occasion might have been brought out to good advantage.

This film could be used not only for college age groups but for high school students or adults. It is more than preparation for marriage; it is excellent mental hygiene.

Who's Boss? Showing time 16 minutes.

The theme of this picture is the married couple who work for the same newspaper and who have careers to further. The woman is the dominant one and is less appealing. The couple realize the competitive situation is dangerous to their marriage and work hard to straighten out their difficulties. They are shown over a period of time in which they make a good adjustment. The woman gives up most of her professional work to devote herself to her children. The man, too, makes some compromises, so that his wife can also use her talents productively in her profession.

The film is good for young people of college age or young married couples. The way that the hero and heroine work out their serious difficulties and the troubles they have along the way seem real and valid. The film holds one's interest and will undoubtedly make for spirited discussion. Skilful leadership will help to make the discussion fruitful.

A 35 mm. filmstrip accompanying each motion picture will aid in stimulating discussion following the showing of each film.

Although produced primarily for college courses in marriage and family living, these films will find acceptance among a variety of adult groups—professional, educational and civic. These films might be better used singly or two at a time, since each film necessitates thorough discussion under skilled leadership.

The photography, narration and direction are excellent.

---

[1] This case was actually decided on Dec. 9, 1948, but it was not published in the Federal Supplement Reporter Series until Oct. 16, 1950.

CURRENT MEDICAL LITERATURE

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1939 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

80:363-532 (Sept.) 1950

Application of Nutrition Research to Everyday Practice. P. C. Jeans. —p. 363.
Growth and Development of Negro Infants: II. Relation of Birth Weight, Body Length and Epiphysial Maturation to Economic Status. A. Kessler and R. B. Scott.—p. 370.
*Vitamin D Intoxication in Child with Rheumatoid Arthritis. J. S. Hyde and J. B. Richmond.—p. 379.
Toxic Lesions of Pancreas. P. V. Véghelyi, T. T. Kemény, J. Pozsonyi and J. Sós.—p. 390.
Primary Sarcoma of Liver: Report of Case. G. Willeford and V. A. Stembridge.—p. 404.
*Pulmonary Toxicity of Wetting Agents Dispensed as Aerosols. G. C. Hall Jr.—p. 408.
Treatment of Patient with Cleft Palate: Present Day Concept of a Pediatric Responsibility. D. B. Coursin.—p. 442.

Vitamin D Intoxication.—Hyde and Richmond report a girl who had had rheumatoid arthritis since infancy. The right knee continued to be the only affected joint until she reached 4 years of age, when, within several weeks, pain, swelling and limitation of motion of the joints of the hands and feet developed. Pain and limitation of motion of the spine also developed. The appetite became poor, and gain in weight was slow. The joint deformities gradually became more pronounced, and weakness and easy fatigability developed. High potency vitamin D was given orally in doses of 2 to 3 capsules (100,000 to 150,000 U. S. P. units) each day, from the development of multiple joint symptoms at 4 years of age to the time of her first admission to the hospital on March 10, 1947. This was a total of five and one-half years of therapy. The authors first saw the child when she was about 10 years of age. During the period of treatment with large doses of vitamin D, anorexia, vomiting, polydipsia, polyuria, nocturia, calcification of blood vessels, of periarticular soft tissue, of conjunctivas and of corneas, hypertension, hypertensive retinopathy and renal insufficiency had developed in the child. Some amelioration of symptoms was noted after the discontinuance of vitamin D therapy, but there was no significant improvement in the renal function after two years of observation, indicating irreversible kidney damage. When vitamin D is used in large doses, the renal function should be studied before and after treatment. The toxic effects are reversible if use of the drug is discontinued soon enough. The symptomatic improvement which is related to the sedative effect of hypercalcemia probably warranted experimentation with massive doses of vitamin D for rheumatoid arthritis in the past, but present knowledge of the toxic effects and the recent information concerning endocrine factors in rheumatoid arthritis should now invalidate massive vitamin D therapy.

Pulmonary Toxicity of Wetting Agents in Aerosols.—Hall says that wetting agents are used for the following purposes: (1) to increase fat absorption in cases of pancreatic fibrosis, (2) as mucigogic agents in the treatment of peptic ulcers, (3) as ingredients of dentifrices, (4) as solvents for penicillin aerosols, (5) to wet down dusts in mines and (6) in combination with sulfonamides to increase the moisture in croup tents in the treatment of children with laryngotracheobronchitis and similar diseases. The two radicals in these compounds are a long hydrocarbon chain, which is the lipophilic or hydrophobic group, and a short SO_4Na group, which is the lipophobic or hydrophilic group. In the experiments described by the author, guinea pigs were used. The various wetting agents were dispensed in concentrations of 1.0, 0.5 and 0.1 per cent, and atmospheric air was used to convert the solution to aerosol. The animals were exposed for eight hours a day for six days. After a week those not already dead were killed and studied. Histological sections were made of the trachea, bronchi and lungs. Sodium laurylsulfate, alkylaryl sulfonate, synthetic primary alcohol sulfate and sulfonated ester of dicarboxylic acid were studied. These were toxic in proportion to their concentration. Toxic effects consisted in degeneration and desquamation of alveolar epithelium. In 0.1 per cent concentration the agents are apparently nontoxic to guinea pigs. Limitation of the concentration of wetting agents to 0.1 per cent in experimental investigation in man is perhaps advisable.

Visammin in Angina Pectoris.—Visammin (2-methyl-5, 8-dimethoxyfuranochromone) is one of the three active crystalline substances that has been isolated from the fruit of Ammi visnaga Lam, a plant which grows wild in the eastern Mediterranean countries. Armbrust and Levine employed the drug in the treatment of 53 ambulatory patients with angina pectoris. The dose was generally 40 mg. three times daily, given by mouth. The patients carried on their usual activities. Placebos identical in appearance were used for a time as controls. About 60 per cent of the patients showed improvement, i. e., used fewer nitroglycerin tablets, had fewer and milder attacks of pain and could walk greater distances. There were undesirable side effects, such as nausea, anorexia and dizziness, in more than half of the patients. These were a real deterrent to the use of the drug in many instances. There is a need for a long-acting coronary vasodilator. Visammin may meet this need in an appreciable number of patients, if the untoward side effects can be controlled. Since the drug has a cumulative effect, an initial dose may be given to obtain an effective blood level, and then the amount of the daily dose may be lowered.

Aureomycin Therapy in Hepatic Coma.—Farquhar and his associates gave aureomycin, in addition to numerous supportive measures, to four patients having acute liver failure with coma. In two instances the liver failure complicated viral hepatitis; in the other two, portal cirrhosis was the complicating factor. In the experience of most observers, the mortality rate in cases of hepatic coma, particularly if the coma follows viral hepatitis, has been high despite many types of supportive treatment. The four consecutive patients with acute hepatic coma showed improvement on receiving aureomycin in addition to supportive therapy. The response to aureomycin was sufficiently striking in the first two cases and in the fourth case to suggest strongly that improvement was due to the activity of this drug. In the fourth case the cessation of coma appeared to be clearly related on three successive occasions to the administration of the drug. This action could have occurred in the intestinal tract or by antibacterial action within the liver itself, or possibly within the circulatory system.

Aureomycin in Chronic Liver Disease.—Shaffer and his collaborators report on a group of 13 patients with chronic liver disease whom they treated with aureomycin. The patients were under observation for four to 15 months. Nine of the patients gave a history of what appeared to be acute viral hepatitis with jaundice at some time prior to the present hospitalization. Another patient, although not having a clearcut history of hepatitis, had been exposed to viral hepatitis during World War II. Two patients had had portal cirrhosis, probably of alcoholic origin. In a patient with hepatosplenomegaly and abnormal hepatic function tests, the causative agent could not be ascertained. The usual dose of aureomycin was 2 Gm. per day for 30 days. In seven cases improvement resulted which may have been related to aureomycin therapy. In six cases there was little or no evidence of benefit from aureomycin. Dermal sensitivity manifested by skin and nail changes was observed in five cases. In four of these, the lesions appeared after exposure to sunlight, indicating the possibility that in some circumstances aureomycin may be a photosensitizing agent. The results of this study suggest that aureomycin therapy may be of value in some types of chronic liver disease.

Hindquarter (Interinnomino-Abdominal) Amputation.—According to Saint hindquarter or interinnomino-abdominal amputation was first performed, although unsuccessfully, by Billroth in 1891. For the following two or three decades the number of cases in which this operation was attempted was small and the mortality rate high. In recent years the mortality rate has been reduced to about 15 per cent. The indications for the performance of this amputation as now established are more or less restricted to tumor formation, involving either the innominate bone itself or the tissues of the upper thigh, bony, soft or articular, to such an extent that a disarticulation through the hip joint obviously could not be expected to result in complete ablation of the disease. The author reports a case of osteosarcoma of the innominate bone with amputation about four months after the appearance of the tumor. The patient left the hospital on his sixteenth postoperative day with the wound completely healed. This the author believes to be the shortest period of postoperative hospitalization yet recorded following this amputation. A roentgenogram of the chest eight weeks after operation showed the presence of metastatic involvement of both lungs, although at this time the patient was feeling well. He died at home about a month later. This case serves to emphasize the paramount neecssity of early diagnosis of malignant disease if the rational treatment of adequate removal of the primary tumor is to be successful.

Placental Barrier in Poisoning.—Martland and Martland cite autopsies on two pregnant women who had succumbed to carbon monoxide asphyxiation. These revealed that carbon monoxide does not cross the placental barrier, because of its rapid fixation within the red blood cells of the mother. This is also evidence against the theory of transplacental transfer of red blood cells between mother and fetus. A doubt is therefore raised as to the correctness of the present theories of Rh isoimmunization. The authors report the first human case in which the placental transfer of barbiturates has been demonstrated by quantitative organ analysis of the mother and her fetus. The barbiturates accumulate in the fetus to a level almost twice that of the mother because of the slower and less efficient detoxication and excretory mechanisms of the fetus. This "pooling" tendency in the fetus of most of the sedatives given by the oral, rectal, parenteral or inhalation routes may explain the increased neonatal morbidity and mortality resulting from the use of such agents during labor. Seventeen children of ten mothers, who had been luminous watch dial painters, were examined for radium deposits. None showed amounts of radioactivity in excess of 0.01 microgram, which is considered the upper limit of normal radioactivity in the human body. This does not prove, however, that the gaseous emanations present in the mother's blood do not cross the placental barrier; should they do so, radioactive deposits in the children would be too small to produce harmful results. Gamma ray measurements were made in all 17 children. The more sensitive breath radon tests were used on three children who showed radioactivity in the gamma ray measurements. These observations should be put on record in view of the present interest in the biologic effects of atomic energy. Internal poisoning by ingestion, inhalation or parenteral injections of long-lived radioactive substances, in which permanent radioactive deposits can be detected and measured during life and after death, is not to be confused with the deleterious effects caused by excessive external exposure to roentgen rays, excessive amounts of radioactive material or the explosion of atomic material. Such external exposures rarely render the person radioactive. Internal poisoning by radioactive substances has been characterized mainly by anemias of the pseudoaplastic type (large doses), radiation osteitis, necrosis of the jaws and temporal bones and osteogenic sarcomas, since essentially all the retained radioactive substances are eventually stored in the bones. When the portal of entry has been chiefly the respiratory tract, bronchiogenic carcinomas have occurred. No effects on the generative organs have been noted, and sterility and genetic mutations are not a problem.

Boeck's Sarcoid.—Riley's study of Boeck's sarcoid is based on 52 patients with generalized sarcoidosis seen at Bellevue Hospital between 1939 and 1949. The average length of follow-up on the entire group has been four years and eight months. The author presents a clinical study of the cases and a review of the literature. Boeck's sarcoid is a chronic, infectious, granulomatous disease, which in this country shows a predilection for young Negro adults. The etiology of sarcoidosis remains obscure. There is a close relation between sarcoidosis and tuberculosis, although its exact nature is not clear. There is no direct evidence that Boeck's sarcoid is caused by the tubercle bacillus. Although the disease may show complete regression, its benignity has been greatly overemphasized. The eventual outcome of this disease and the development of directly related complications are uninfluenced by any therapy. The mortality in this series has been almost 20 per cent; in an additional 13 per cent of the patients, clinically active tuberculosis has developed during the period of follow-up. These figures do not include the high percentage of patients with irreversible ocular and pulmonary damage. The term "benign lymphogranulomatosis" is misleading by its implication and probably should be abandoned.

*Seminal Vesiculitis: Disease Entity Sometimes Confused with Appendicitis. M. Russell.—p. 518.

Seminal Vesiculitis Confused with Appendicitis.—A congested or inflamed seminal vesicle may simulate appendicitis in young men. A postoperative quest for the source of the recurrent abdominal pain will lead to the adnexa in the male almost as often as in the female. Seminal vesiculitis, even when focal and primary, occurs not as a local lesion but always as a stage of generalized infection of the genital tract. It is most commonly an ascending infection, complicating urethritis or prostatitis. When the presenting symptom is pain in the right lower quadrant associated with nausea, vomiting and elevation of temperature, it may well be confused with appendical inflammation. However, the vesicular pain is usually dull and aching rather than sharp and stabbing. The initial epigastric distress which precedes the pain of appendicitis is seldom present, and the nausea and vomiting are not as constant and severe. With concomitant urethral involvement, a discharge may be present before the onset of the abdominal symptoms. In bilateral vesiculitis, which is more frequently encountered than unilateral involvement, the differential diagnosis is less difficult. Palpation of the abdomen reveals tenderness in the lower quadrants. Where the left vesicle is minimally or not at all involved and the symptoms are confined to the right side, confusion and possible error may result. Careful rectal examination may furnish a clue to the confusing picture of abdominal pain. The inflamed vesicles may become distended with purulent material and edema fluid so that they can be palpated as sausage-like projections above the prostate gland. The pressure of the examining finger on the vesicle will produce local pain and will also reproduce the abdominal pain. This latter observation is almost diagnostic.

ACTH and Cortisone in Renal Disease.—Thorn and co-workers treated 26 patients with renal disease with adrenal hormones Four patients with acute glomerular nephritis were given 80 to 100 mg of pituitary adrenocorticotropic hormone (ACTH) daily for five to 13 days, the total dose ranging from 0 18 to 1 20 Gm Seven patients with subacute or chronic nephritis were treated with pituitary adrenocorticotropic hormone or cortisone, the total dose ranging from 0 36 to 2 2 Gm Six patients in the nephrotic stage of chronic glomerular nephritis were likewise treated with one drug or the other, the total dose ranging from 0 40 to 2 8 Gm Six patients with lupus erythematosus disseminatus had evidence of renal disease manifested by albuminuria and hematuria They were treated with pituitary adrenocorticotropic hormone in doses of not less than 100 mg daily, the total dose ranging from 0 90 to 7 5 Gm One to four courses of treatment were given, a single course usually lasting for two weeks Three patients with dermatomyositis and proteinuria were treated with both hormones There was no conclusive evidence in the small series of patients that these agents exert any beneficial effect on the over-all course of acute, sub acute and chronic nephritis Pituitary adrenocorticotropic hormone therapy appeared to be an effective method of inducing diuresis in patients with the nephrotic syndrome Often diuresis may be induced by a relatively short period of treatment Metabolic studies of patients with nephrosis treated with both hormones revealed differences in response of respiratory quotient, thyroid function, cholesterol and phospholipid levels from the response under similar conditions in normal persons and in patients with Addison's disease

Liver Insufficiency in Diabetes Mellitus.—Frankel and co workers performed various liver function tests on 139 diabetic patients and found 46 with abnormal reactions The hepatic insufficiency could be explained by factors other than diabetes mellitus, such as chronic alcoholism and cardiac disease with episodes of failure in 28 patients Diabetes was the only disease present which could explain the impaired liver function in the remaining 18 patients The hepatic dysfunction varied directly with diabetic control Diagnosis of cirrhosis and diabetes mellitus was made in 36 of 3,543 patients who were admitted to a Veterans Administration Hospital Thirty-one of the 36 patients were chronic alcoholics The diabetes preceded cirrhosis in 15 patients, while in 21 the reverse was true All except one of these 15 patients had been a heavy consumer of alcohol for many years There were six patients whose diabetes mellitus had been diagnosed five years or more before cirrhosis Diabetes was observed to be the only possible causative agent for the cirrhosis in only one patient, an incidence of 0 028 per cent Fourteen of the 21 patients whose diabetes preceded cirrhosis required insulin to control the hyperglycemia Six of the 15 patients whose cirrhosis preceded diabetes required insulin The incidence of hepatomegaly and fatty infiltration in adults with diabetes mellitus is low Hepatic dysfunction in diabetes mellitus is of low incidence but is transient and seldom leads to permanent damage

Suffocation in Poliomyelitis.—Sjoberg discusses the enthusiasm for tracheotomy in bulbar poliomyelitis which has swept over the United States in recent years In Stockholm the problem became acute during 1949 when there were many cases of severe bulbar poliomyelitis The author agrees with the opinion prevailing in the United States that the majority of fatalities in the early stages of poliomyelitis are due to suffocation and not to circulatory paralysis The mortality rate for patients treated in Sweden with the respirator during the 12 year period 1934-1945 was 86 per cent (119 survived of 834) Of the 14 patients subjected to tracheotomy at Sjoberg's hospital, 12 survived Tracheotomy is indicated in the following five groups 1 Peripheral respiratory paresis with retention of secretion 2 Aspiration (of saliva and vomitus) in purely bulbar cranial nerve lesions (above all, in paralysis of the vagus) 3 Bilateral paralysis of the laryngeal abductors combined with bilateral paresis of the pharynx 4 Spinobulbar lesions, manifesting themselves in a bilateral paresis of the pharynx (plus, in certain cases, nuclear paresis of the accessory nerve plus injuries to the first and second cervical segments of the spinal cord). Suffocation in these cases is chiefly characterized by the angle, or rope dent symptom, which constitutes an alarm signal The patient risks being strangled by a contracture or tonus excess in his nonparalyzed antagonistic muscles, which draw the hyoid bone backward and upward If, in addition, a nuclear paresis of the accessory nerve occurs, the rope dent symptom is further accentuated, and the patient's condition is aggravated 5 Cases in which the operative treatment is applied prophylactically The respirator treatment may be harmful and can even hasten death by suffocation if broncho scopic suction with or without tracheotomy is not applied simultaneously Postural drainage with oxygen or an oxygen-carbon dioxide mixture (carbogen) is absolutely necessary During the first and sometimes even during the second week the fluid balance must be carefully controlled and the liquid administered only parenterally in isotonic or hypertonic form Dextran and blood transfusions proved effective in the initial shock condition which often appears in the hours following tracheotomy

Tracheotomy in Poliomyelitis—A total of 166 patients with poliomyelitis were admitted to the New Haven Community Hospital in 1949 Of these, 17 had bulbar poliomyelitis, and 10 of them were subjected to a tracheotomy Strobel and Canfield believe that tracheotomy should be considered whenever a patient in a respirator exhibits signs of bulbar involvement or shows persistent cyanosis or struggling Patients not in a respirator require therapeutic tracheotomy when they are unable to keep the airway free of secretions, as evidenced by moist rales, choking and cyanosis Most patients with bulbar involvement who are not in a respirator will complain of difficulty in swallowing. A prophylactic tracheotomy should be considered whenever early and progressive bulbar signs are present and before the patient has difficulty, or when a long siege in the respirator seems probable, even though no bulbar signs are present. A patient with severe respiratory paralysis may have difficulty handling pharyngeal mucus because of inability to cough effectively. A certain number of these prophylactic tracheotomies might be life-saving. However, it is impossible to forecast how many of the patients in a respirator will have enough difficulty to need a tracheotomy, and some needless tracheotomies might be done. In a desperately ill patient in need of a tracheotomy, it is probably more dangerous to delay the tracheotomy than to perform it. The authors admit that five of the 10 patients in whom they performed a tracheotomy died, but in none of these patients was death attributable to the operation. The tracheotomy was probably life-saving for every one who survived. Earlier tracheotomy in three of the five who died might have been life-saving.

Hereditary Deafness in Otosclerosis.—From an earlier study on 581 cases of deafness, Kopetzky concludes that a chemical abnormality in the blood is the evolutionary basis of the lesions of otosclerosis. In familial groups, biochemical changes in the blood were so similar that a study of the hereditary character of deafness in otosclerosis was begun. In one case, the parents were unaware of having any loss in hearing acuity; nevertheless, their blood showed that they carried a metabolic mechanism defect. They had transmitted this defect to their child, who was a congenital deaf-mute. The child had both pyruvemia and hypercholesteremia. The father had only pyruvemia, and the mother's blood showed both pyruvemia and hypercholesteremia. The hereditary character of deafness is discussed on the basis of 25 deaf-mutes, 5 severely deafened children and 25 children with limited hearing. The relations between the biochemical abnormalities in the blood and the cellular abnormality of the otic capsule in otosclerosis are discussed. Persons with congenital deafness have hereditary defects of carbohydrate metabolism which lead to otosclerotic lesions on the otic capsule in intrauterine life, or they carry in their blood the biochemical-pathological changes of otosclerosis, and lesions develop after birth. The blood biochemistry gives an explanation as to why the cellular pathological changes of the otic capsule must result. Heretofore, this explanation was impossible, although the evolution of the pathological picture was known. The author suggests a diagnostic triad which does not depend on any statement of the patient or his family concerning deafness in the family. He discusses the possibility of replacement therapy, to supply the essential items which are indicated by the presence of pyruvemia alone or pyruvemia and hypercholesteremia.

Sterilization of Water in Hydrotherapeutic Tank by Ultraviolet Rays.—Jern and Currence say that, although ultraviolet rays have been used for the sterilization of drinking water and for the disinfection of swimming pools, they could find no record of the underwater use of ultraviolet rays as a sterilizing agent in hydrotherapeutic practice. They conducted studies to determine the efficacy of underwater ultraviolet rays in the disinfection of hydrotherapeutic tanks. Various organisms, such as Escherichia coli, Staphylococcus aureus, enterococci, psuedoanthrax bacilli and Trichophyton mentagrophytes were added to tank water in a test of the action of ultraviolet rays. Under conditions simulating hydrotherapeutic treatment, a considerable portion of the seeded organisms were destroyed prior to exposure to ultraviolet rays by a temperature of 44 C. by chlorine (0.06 to 0.2 parts per million of tank water) and by the water itself. In order to obtain a maximum survival of bacteria for an estimation of the true bactericidal power of ultraviolet rays, dechlorinization of water was accomplished by the addition of sodium thiosulfate or broth. Sodium thiosulfate appeared to be preferable to broth. Various numbers of the micro-organisms, up to 2,000,000 per milliliter of water, were subjected to 20 minutes of exposure to ultraviolet rays, with complete sterilization. The authors conclude that the underwater use of ultraviolet rays can be recommended as a reliable sterilizing procedure. For optimum effects the water should be simultaneously agitated to permit exposure to the rays of every particle of contaminated water.

Sludged Blood After Severe Burns.—In studying sludged blood following severe thermal burns, Brooks and his associates used rabbits and dogs as experimental animals. Observations were also made on burned patients. It was found that there are definite physical alterations in the circulating blood after burns. There is intravascular agglutination of red blood cells into rigid, basic masses. These clumps are usually first seen in the postcapillary venules. White blood cells stick to the vessel walls soon after the burn. Increased plasma viscosity is evidenced by the progressive slowing of the rate at which clumps of red cells turn over as they flow along, by the loss of laminar flow and by the absence of immediate, homogeneous mixing of venous streams as they join. The flow rate decreases to as little as one-third the preburn rate. Reduced rates of flow result in sacculation and tortuosity of vessels and in multiple, small thromboses of small arterioles and venules. This is accompanied with increased anoxia of surrounding tissues. There is leakage of fluid through vessel walls. Red blood cells are present extravascularly, without direct evidence of ruptured vessels. Small hemorrhages occur, and red blood cells have been seen in the phagocytes of spleen, liver and bone marrow after recent burns. The authors discuss mechanisms by which sludging changes following burn may lead to shock. There is no evidence to support the hypothesis that histamine is the "toxin" of burn shock. The evidence presented does not rule out the possibility that some toxin exists but strongly indicates that physical changes in the circulating blood may be the same as what previously has been called "toxic effect." The extravascular (diapedesis and hemorrhage), intravascular (in "thrombi") and phagocytic loss of red blood cells from the circulating blood which accompanies the sludging changes following burn may be an important factor in postburn anemia. The chemical and/or immunologic factors involved in the initiation of the sludging process and in the depositing of the sticky coating on red blood cells after burn have yet to be determined. The sludging process must be investigated before one can determine a reasonable and adequate treatment for burns.

Prostatic Cancer: Further Investigation of Hormonal Relation.—Brendler and his collaborators describe the clinical and laboratory observations in three patients with advanced prostatic cancer who received testosterone propionate. The dose varied from 25 to 100 mg. daily, and the drug was given for periods up to two months. Two of the three patients had extensive secondary involvement of bone, and one had previously been castrated and had received estrogen. The authors were impressed with the general improvement shown by the two patients with metastatic prostatic cancer while they received testosterone. Pain in the bones was considerably lessened in the patient who complained of this initially and did not develop in either of the other two. As evidenced in roentgenograms, metastasis did not develop in the patient initially free from it, nor did a remarkable change occur in the two patients with metastasis. The serum acid phosphatase showed a further increase in the two patients with osseous metastasis but not in the one without it. Perhaps occult bony metastasis can be diagnosed by observation of the response of the serum acid phosphatase to a short course of androgen injections. Further investigation of the role of androgens in prostatic cancer is warranted. In cases of metastatic cancer of the breast in the female, both androgens and estrogens have been used, androgens apparently exerting a more beneficial effect in younger women and estrogens in the older age group. Androgens appear to affect osseous metastasis predominantly, whereas estrogens primarily influence the soft tissue metastasis and the primary growth itself. Perhaps an analogous situation exists with reference to prostatic cancer.

Carcinoma of the Prostate Gland: Results of Conservative Management.—Reynolds and associates found that conservative management of 104 patients having carcinoma of the prostate gave encouraging results. The patients were seen at frequent intervals and treated with orally administered, enteric-coated diethylstilbestrol. Osseous metastasis was disclosed in 39. Most patients had an advanced neoplasm when first examined. Originally the daily dose was 3 mg. or less. For the past five years, 5 mg. of the drug has been given once daily. Dosage was increased if necessary, and up to 50 mg. was given daily. In some instances the dose was reduced to 2 or 3 mg. daily, after prolonged therapy. The patients who had only slight or no urinary obstruction were treated only with antiandrogenic hormone. In some patients the drug was used in conjunction with indwelling urethral catheter drainage, which was continued for two weeks to four months. Nine patients regained their ability to void; another six patients were unable to void and were subsequently relieved by transurethral resection. This method of managing elderly patients is highly satisfactory because, if the need for transurethral resection becomes evident later, the procedure can be performed when the patient is a better surgical risk than when first seen. Resection was performed in 56 patients. A second resection was required because of regrowth of malignant tissue and subsequent urinary difficulty in 13 patients. Five of these needed a third operation, which made a total of 74 transurethral resections. There was one surgical death. There were two patients in whom thrombophlebitis developed postoperatively and another two patients who had persistent stress incontinence. The authors believe that the patients who had stress incontinence were subjected to a resection that was too radical. The authors subsequently learned to depend more on the antiandrogenic hormone treatment. Of the 104 patients, 81 are alive, 18 are dead and 5 have not been traced. The average survival time of 81 living patients was 34.7 months, for those treated more than one year, 41.1 months. Of the total of 104 patients, 22 survived more than five years, and of these, 16 are still living. The authors conclude that prolonged control of prostatic cancer can be accomplished by the oral administration of antiandrogenic substance.

Studies on Terramycin.—Terramycin is an amphoteric substance forming crystalline hydrochloride and sodium salts; it does not deteriorate during long standing at room temperature at a *p*H under 5; it is active in vitro against staphylococci, Bacillus subtilis and a number of gram-negative bacilli. Bliss and her associates found terramycin effective in the control of infections induced in mice with hemolytic streptococci, pneumococci, Klebsiella pneumoniae, Salmonella typhosa and other organisms. Samples of terramycin hydrochloride were tested at the laboratory of the Johns Hopkins University School of Medicine. The sodium salt was compared with the hydrochloride in a few in vitro tests. As there was no difference in the behavior of the two, the sodium salt was not tested in vivo. The authors found that terramycin inhibited the growth of most of the bacteria tested at slightly lower concentrations than aureomycin. Oral administration of a single dose of terramycin hydrochloride to two human subjects resulted in measurable levels of the drug in the blood and urine for at least 24 hours. Terramycin was more effective than aureomycin in the therapy of K. pneumoniae and Hemophilus influenzae infections in mice but was less effective in pneumococcic and hemolytic streptococcic infections.

Surgical Treatment of Portal Hypertension.—Longmire performed portacaval shunt operations on 15 of 18 patients who were treated surgically for portal hypertension at the Wadsworth Veterans Hospital. The shunt was established by splenorenal anastomosis in eight of the 15 patients. Two of the eight patients are well; four are considered improved, and two died. The portal vein was anastomosed to the side of the inferior vena cava in the remaining seven patients. Two of these patients are considered improved; one is unimproved, and four died. Total gastrectomy and esophagojejunostomy was performed for hemorrhage on one patient who has had no further bleeding in the three years since the operation. Two patients were treated by splenectomy alone because a satisfactory vein for anastomosis could not be found in the splenic pedicle. One of them showed improvement over a short postoperative period, while the other was unimproved. Of eight patients with intrahepatic block who were subjected to portacaval shunt, four are improved, one is unimproved and three died. Of 10 patients with extrahepatic block, six are improved postoperatively, one is unimproved and three died. Survival time of the six patients who died after portacaval shunt varied from three days to four months. Death resulted from thrombosis at the site of anastomosis in two instances, from hepatorenal failure in one, from hepatic failure in one, from extensive pancreatic necrosis in one and from closure of anastomosis in one.

Results of Gastric Resection and Vagotomy in Duodenal Ulcer.—Stevens and co-workers report on 132 patients with duodenal ulcer who were subjected to surgical treatment. The postoperative follow-up period was approximately two years. So-called complete vagotomy, with or without supplemental gastroenterostomy, was performed on 43 patients. Conventional gastric resection was done in 47 patients. Hemigastrectomy and so-called subtotal vagotomy were performed on the remaining 42 patients. Good results were obtained in 33 patients (78 per cent) of the first group, in 42 (90 per cent) of the second group and in 38 (90 per cent) of the third group. Results were unsatisfactory in 10 patients (22 per cent) of the first group, in five (10 per cent) of the second group and in four (10 per cent) of the third group. There were no deaths following gastric resection or hemigastrectomy with subtotal vagotomy. There was one operative fatality from perforation of the esophagus, following vagotomy. Stomal ulcer developed in one patient following gastric resection, in one following hemigastrectomy with subtotal vagotomy and in three following vagotomy and gastroenterostomy. Histamine-induced secretion of gastric acid was greatly reduced after adequate gastric resection and after hemigastrectomy with partial vagotomy, whereas this effect was relatively minimal after vagotomy. There was no instance of gastric retention in patients who had undergone gastric resection and hemigastrectomy or in those who had had partial vagotomy. Of patients subjected to a vagotomy alone, 70 per cent had six to 24-hour retention. The incidence of retention after gastroenterostomy and vagotomy was 17 per cent. Results obtained with gastric resection and with hemigastrectomy with subtotal vagotomy were better than those obtained with vagotomy alone.

Differential Diagnosis of Poliomyelitis.—According to Woodcock and his co-workers early diagnosis in poliomyelitis has prompted physicians to "err on the side of safety" by diagnosing poliomyelitis when suggestive symptoms occur. They present data accumulated during the summer and fall of 1949 in a diagnostic and treatment center for poliomyelitis. A total of 140 patients referred by physicians were admitted with a tentative diagnosis of poliomyelitis. Of these, 110 (78.5 per cent) were found to have poliomyelitis. Almost any child with a gait disturbance or loss of function of an extremity was suspected of having poliomyelitis. The following manifestations should suggest that other diagnoses be considered: (1) severe pain, localized tenderness, or swelling of affected extremities (2) pronounced lymphadenitis or lymph node enlargement, (3) fever, particularly of a septic nature, (4) a critically ill, irrational or comatose state, (5) dehydration, (6) convulsions, (7) prolonged illness with subsequent paralysis and regional sensory changes, (8) upper motor neurone lesions and (9) ataxia. The authors list 58 entities that have been confused with poliomyelitis These included mastoiditis, pneumonia, mumps, rheumatic fever osteomyelitis, torticollis, retropharyngeal, cervical or brain abscesses, epilepsy, herpes zoster, cerebral malaria, encephalitis resulting from vaccination, postdiphtheritic neuritis, multiple sclerosis, transverse myelitis, various forms of meningitis, infectious polyneuritis and Coxsackie virus infections. The hazards of exposing children in whom the diagnosis is unconfirmed necessitate adequate isolation facilities pending the establishment of a definitive diagnosis in any center caring for patients with poliomyelitis.

*Relationship Between Truck and Tractor Driving and Disorders of the Spine and Supporting Structures. W. I. Fishbein and L. C. Salter. —p. 444.

Truck and Tractor Driving and Disorders of the Spine.—The survey on which Fishbein and Salter base this report was undertaken to throw light on the relationship between disorders of the spine and supporting structures and the driving of trucks and tractors. A questionnaire, so worded as to avoid specific reference to the seating factor, was sent to all the orthopedic surgeons in the United States. To the 1,474 questionnaires mailed out, replies were received from 378, or about one fourth. The widespread interest in the subject is indicated by the fact that 327 requested a copy of the report. Question 3 read: "Which of the following disorders do you believe may have been caused in whole or in part by driving trucks or tractors?" The disorders listed and the number of positive answers were as follows: spinal injuries 25, herniated disks 95, osteoarthritis 103, spondylitis 41, subluxation 20, sacroiliac strain 72, traumatic fibrositis 109 and coccygodynia 82. Thirty-seven disorders in addition to those listed were named in the replies. These included lumbosacral strain, pilonidal sinus or cyst, sciatic neuritis, low back pain, lumbosacral arthritis, fibrositis, myositis and mechanical backache. These authors feel that, with more than 10,000,000 trucks and tractors being operated in the United States, exclusive of those in the Armed Forces, the health hazards of driving such vehicles constitute a major medical problem that have not received the attention and study they deserve either by the medical profession or the manufacturers of such equipment

*Sodium Amytal as Causative Factor in Some Cases of Prolonged Insulin Coma R. B. White, R M Gilliland and J. R Ewalt—p 245.

Amobarbital Sodium and Prolonged Insulin Coma.—White and his collaborators say that patients in whom subshock or shock has been produced by insulin may require some rapidly acting hypnotic for sedation or for facilitation of therapeutic interviews. Because amobarbital (amytal®) sodium is commonly used for these purposes, they call attention to possible dangers associated with the combined use of these two drugs. They cite three patients of their own and a patient reported by Kalichman in 1948 in whom a critical condition developed when amobarbital sodium was given shortly after insulin shock. The first patient remained in a critical condition for 24 hours. He showed the usual signs of prolonged coma, including hyperpyrexia, repeated clonic spasms and stertorous breathing. Two patients had signs of prolonged coma until the third and fifth postcoma days. The authors suggest the following possible explanations of the difficulties observed: (1) masking of the signs of hypoglycemia by the amobarbital sodium, (2) insufficient precaution and care by the staff and (3) possible dangerous synergism between amobarbital sodium and insulin. Evidence implicates the barbiturates as a contributing agent in increasing the likelihood of prolonged coma when insulin and barbiturates are used simultaneously The authors recommend increased caution in the simultaneous use of these two drugs.

Diagnosis of Bladder Tumor.—Berry and Hamilton say that, in cancer of the bladder, the exact nature and extent of a lesion must be determined before operation. They agree with Milner that a biopsy specimen obtained by the resectoscope, properly taken and correctly prepared, gives accurate information on bladder tumors and compares favorably with those taken at operation. The taking of a biopsy specimen should be carefully planned and meticulously carried out. One piece of tissue is rarely enough. Sections should be taken to show not only the papillary portion of a tumor but its base and, in some cases, the surrounding tissue as well. The tissue fragments must be sectioned so that the mucosal surface, submucosa and muscle are shown The surface to be cut is painted with merbromin, which is applied with a swab The merbromin is not removed by fixation and dehydration and does not interfere with staining of the sections If the surgeon does not mark the surface to be cut, then he must show the pathologist how the specimen should be embedded, because, in many cases, if the biopsy is small, it is impossible to tell one surface from another after fixation in formalin. Accurate preoperative diagnosis of tumors of the bladder is possible in almost every case with the information obtained by cystoscopic examination, resectoscope biopsy and bimanual examination.

Treatment of Early Syphilis.—Wright and his co-workers report on studies undertaken at the Venereal Disease Research Laboratory to determine the results of administration of varying amounts of procaine penicillin G. Average penicillin levels of patients recently treated with one-injection and three-injection schedules are presented. Post-treatment observations for more than a year prove that a single injection of 300,000 units of procaine penicillin G in peanut oil containing 2 per cent of aluminum monostearate does not provide an optimum cure rate in early syphilis. The schedule of 600,000 units daily for three days offers an effective regimen for the ambulatory treatment of early syphilis.

Poliomyelitis: Hypothesis of Its Etiology.—Cumming presents evidence that poliomyelitis is the result of a carrier state and of autoinoculation of nerve tissue through a wound. He points out similarities between rabies and poliomyelitis. First, both are neurotropic; second, for the disease to occur, there must be disruption or severing of nerve fibers, and the virus of the saliva-rabid animal or poliomyelitis carrier must have sufficient concentration to make direct contact with the axon protoplasm of the disrupted nerve fibers; third, the pathological process of both is limited to the central nervous system; fourth, occurrence of the disease is rare in proportion to the number of wound exposures, and, fifth, there is no generalized inflammatory involvement at the portal of entry in either disease. Rabies virus is strictly neurotropic, since it has no phase of multiplication except in nerve tissue. It must be transmitted from nerve tissue to nerve tissue, with only a brief passive salivary phase. Poliomyelitis virus, on the other hand, has an extraneural multiplication or growth phase. It is found in the oropharynx, along the intestinal canal and in alvine discharges. Hence, it is propagated by dissemination of the virus from person to person by direct and indirect contact. In a poliomyelitis outbreak in 1945, 59 patients were studied with regard to oral and surface injuries. Twenty-one had a history of oral injuries and 33 of surface injuries within four weeks of the onset of symptoms—a 92 per cent injury rate. The control of poliomyelitis involves first the prevention of the spread of virus from person to person. This requires the same measures of personal hygiene and sanitation which are applicable to the common contact infections. Cleansing of accidental wounds, which serve as portals of entry to severed nerve fibers, is the second important factor in prevention of the autoinoculation of the virus of poliomyelitis.

Berylliosis.—Nachtwey and his associates summarize the present status of knowledge on berylliosis and report a man, aged 35, who was in the electrical business and who had worked with fluorescent lamps, blowing the glass and coating the tubes. He had a nonproductive cough for many years. During the fall of 1948 he noticed dyspnea on exertion and fatigue. He also had bilateral thoracic pain of pleuritic nature. For several months before coming to the Mayo Clinic he had noticed slight edema of the ankles. Diuretics had been administered at home without appreciable effect on the edema. Examination revealed persistent fine rales over the lower two thirds of both lung fields. At the base of the nail on the left fourth finger there was a healed scar, which the patient said was the result of a lesion which would occasionally swell, drain and then heal over. He thought this lesion had followed a cut by a piece of fluorescent glass. An abnormally enlarged lymph node was found in the left axillary space. This node was removed in April 1949. Microscopic examination revealed that it was a granuloma, and spectrographic analysis disclosed beryllium. The patient was advised to avoid all contact with beryllium powder or fumes and to avoid overexertion. The authors stress that, because berylliosis is an uncommon disorder, its presence is not likely to be suspected. Failure to recognize the cause of the trouble and failure to remove the patient from further exposure may result in irreparable damage to his health or cause his death.

Terramycin in Pneumonia.—Pratt reports a Negro woman, aged 27, in her sixth month of pregnancy. Radiologic examination revealed an irregular area of consolidation in the lower lobe of the left lung. This appeared to be segmental pneumonia, involving the medial portion of the left lower lobe. The patient was given 500 mg. of terramycin hydrochloride orally every six hours, starting at 5 p. m. on April 25, 1950. She was given nasal oxygen throughout the night and 1 grain (60 mg.) of codeine phosphate every four hours for chest pain. The next morning her temperature dropped to 98.2 F., the pulse rate was 100, respirations 26 and the fetal heart rate 136. The chest pain was nearly gone. The cough was decreased and the sputum no longer blood tinged. The condition of the chest was unchanged. The patient stated that she felt well. The oxygen and the codeine were discontinued and were not used throughout the remainder of the hospital stay. Roentgen examination of the chest on April 27, 1950, revealed no significant change, but definite clearing of the area of consolidation was seen on May 1, 1950. The patient was discharged on May 3, 1950, as clinically well. Terramycin is apparently as effective as streptomycin and does not have the serious side effects.

Cardiac Catheterization. L. B. Ellis and R. A. Bloomfield.—p. 339.

Renal Changes in Gout.—Brown and Mallory report pathological changes in the kidneys revealed by necropsy in five proved cases and one unproved case of gout. All kidneys showed significant or pronounced benign nephrosclerosis and deposits of urates in the medulla, probably originally in the collecting tubules. These observations conform to those of previous studies. Renal lesions presumably specific for gout were observed in one case, but no definite history of acute arthritis was obtained and no tophi or joint lesions were observed at necropsy. This case may have been one of "primary renal gout." Extensive chronic pyelonephritis was revealed by necropsy in two of the six cases; small focal areas of healed pyelonephritis were observed in one case, and observations in another case were suggestive of pyelonephritis. There was frequent association between tubules blocked by urates in the medulla and abscesses nearby or pyelonephritis in the cortex above. It is suggested that tubular blockage by urates predisposes to pyelonephritis, which may contribute to the renal damage commonly observed in gout.

Plasmacytoma of Lymph Node.—Simon and Eidlow report a man aged 52 with a painless swelling in the right inguinal region of four weeks' duration. A well demarcated lymph node was removed under local anesthesia. Biopsy revealed a plasmacytoma of the lymph node. Roentgenograms of the ribs, long bones and skull failed to reveal any pathological change. The urine showed no Bence-Jones protein, but bone marrow and blood protein studies were not done. The patient received irradiation to the right inguinal and iliac regions. One year later he was seen again because of slight recurrent swelling in the right inguinal region, but permission for another biopsy was refused and the patient was not seen for two years. When seen again he had signs of multiple myeloma. Bence-Jones bodies were demonstrated in the urine. Roentgenograms revealed pathological fractures of the ninth and tenth ribs, with many vacuolated and honeycombed areas of rarefaction in the left humerus and in the left scapula. The patient died 47 months after the lymph node biopsy. It is possible that the disease originated in the lymph node and later spread, but it is equally possible that the bone marrow was involved at the time of lymph node biopsy without roentgen evidence of bone destruction. Plasmacytoma in lymph nodes carries a grave prognostic significance and is usually followed, after varying periods, by clinically manifest multiple myeloma.

Cholinergic and Anticholinergic Drugs.—According to Grimson, drugs which stimulate the cholinergic pathways of the parasympathetic nerve supply to the gastrointestinal tract (cholinergic agents) and drugs which block these pathways (anticholinergic agents) are useful in treatment of functional disorders or diseases. The urethane derivative of beta-methylcholine chloride (urecholine®), given in doses of 2.5 mg. subcutaneously at four hour intervals, or 30 mg. by mouth taken on arising and 15 or 29 mg. midmorning and midafternoon, for prolonged periods up to two or more years proved most effective and aided treatment of megacolon, diabetic neuropathy with abnormal intestinal function, postvagotomy disturbances, abdominal distention or ileus and urinary retention following pelvic surgery or chordotomy. Beta-diethylaminoethyl xanthene-9-carboxylate methobromide (banthine®), given in doses of 100 mg. by mouth or 10 mg. subcutaneously or intramuscularly, proved most effective and aided treatment of peptic ulcer and to some extent several disorders or diseases of the small bowel and colon. Urecholine® is an effective agent for treatment of gastrointestinal disorders associated with diminished motor activity, and banthine® is an effective agent for treatment of disorders which, like peptic ulcer, are associated with excessive motor activity.

Chloramphenicol in Ulcerative Colitis.—Bercovitz treated 24 patients with chronic ulcerative colitis with chloramphenicol (chloromycetin®). Three grams daily were observed to be the most effective dosage. Thirteen patients showed pronounced improvement during the first month of observation. There was a prompt and often dramatic decline in the number of bowel movements, with normally formed stools, no blood or mucus, good sphincter control, no night movements and no abdominal discomfort. From a clinical standpoint these 13 patients became essentially normal. Sigmoidoscopy revealed that the mucosa was normal, and submucous petechiae were not observed. Three patients were moderately improved. Eight patients did not show essential change. Though initially they responded in mild degree to the drug, this response was usually only temporary, and in no instance was it comparable to that of the first group. Chloramphenicol therapy proved of definite value also in subsequent relapses. The prompt administration of the drug prevented the usual decline associated with a tendency to relapse and often resulted in rapid response. No patient relapsed to the level of the original severity of the disease. Chloramphenicol may be used repeatedly and for prolonged periods without toxic side-reactions. After the initial period of treatment for about one month, an interrupted schedule of treatment for relatively short periods proved superior to constant and prolonged administration. The patients continued to be improved, both symptomatically and sigmoidoscopically, for extended periods atfer administration of the drug was discontinued. Final clinical evaluation can be made only after a period of about five years, when sufficient time has elapsed to account for spontaneous remissions, seasonal variations, psychoemotional situations and other conditions which may influence ulcerative cholitis.

*Hemophilia Simulating Acute Surgical Abdomen M Shelton and H H Hussey —p 233

Hemophilia Simulating Acute Abdominal Conditions. —Shelton and Hussey point out that the bleeding of hemophilia is in the deep structures, muscles, bones and joints. This may help to distinguish hemophilia from other hemorrhagic diseases, such as thrombopenic purpura, in which blood often oozes from the mucous membranes Intra-abdominal hemorrhage is one of the most serious forms of bleeding in hemophilia. There may be hemorrhages into the wall of the colon or the mesocolon, where the signs are those of partial obstruction, and into the iliopsoas muscle, where the signs resemble those of acute appendicitis. The authors describe two cases which exemplify the difficulties that may be encountered when a hemophilic patient complains of pain in the lower part of the abdomen. At the time of their admission both patients were known to have hemophilia. It was not known if their symptoms were due to a bleeding episode or to acute appendicitis. In the first case, intestinal hemorrhage seemed most probable, because of the tarry stools and coffee ground vomitus and signs of generalized peritoneal irritation. The treatment was directed to correction of the coagulation defect, and the rapid regression of symptoms substantiated the impression that intra-abdominal hemorrhage was the sole cause. In the second case, the condition progressed so rapidly that surgical intervention appeared imperative. The patient was prepared with antihemophilia globulin, and the abdomen was explored as soon as the coagulation time approached normal. Intra-abdominal hemorrhage was found, although the clinical symptoms were those of acute appendicitis. Criteria for the diagnosis of hemophilia include a familial and personal history of bleeding, increase in clotting time of venous blood and return of the clotting time to normal after administration of antihemophilic globulin. During an acute episode of bleeding, local measures include application of cold to the area, pressure bandages, fibrin foam, thrombin, electrocautery, gelatin, epinephrine, muscle or placental extracts and application of globulin. If the hemorrhage is not controlled by local measures, or if there is internal bleeding, general therapy should be instituted. Transfusion of 500 cc. of whole blood usually corrects the coagulation defect. A transfusion of 200 mg. of antihemophilic globulin fraction I, dissolved in 5 to 10 cc. of isotonic sodium chloride solution is as effective as whole blood, if there is no anemia.

Distinction Between Loving and Being Loved L J. Saul —p 412

Unsatisfactory Results of Psychoanalytic Therapy.—Oberndorf found that the two leading psychoanalytic journals contain, over the past 10 years, practically no articles reporting the results of psychoanalytic treatment. One of the most recent books on technic also fails to mention results In psychoanalytic treatment the aim is to relieve the patient of symptoms through a radical change in the structure of his personality Regression to very early periods of life may occur in the course of psychoanalysis, but the repeated reliving of these events does not necessarily produce an assuaging abreaction. The original neurosis may be replaced by a neurotic search for analytic interpretations. The author suggested in 1942 that a case be reviewed in consultation if the patient has been under classical psychoanalytic treatment four to five hours a week, for a total of more than 300 hours. Such a consultation might occur with a group of three experienced psychoanalysts. Such groups might decide if the patient should continue with the same analyst, be considered not well adapted to psychoanalysis or be referred to a second analyst because of transference difficulties leading to therapeutic stasis. It should be recognized that one analyst may fail to achieve satisfactory results with a patient where another may succeed. The author discusses measures that could be undertaken to improve the disappointing results of psychoanalysis. He feels that a questionnaire addressed to analysts as to their experience and opinion would be worth while. The value of the questionnaire will depend on the willingness of analysts to sacrifice some complacency and pride, to discard much of prevalent secrecy and to devote adequate time and thought to the replies The questionnaire method might eventually also be extended to patients who have completed their analyses and whose retrospective reactions might supply much valuable insight and data However, the fairest and probably the most productive approach is the study of each unsatisfactory psychoanalysis by the analyst in conference with his colleagues

Thyroid and Menstrual Bleeding —Deisher emphasizes the frequent association of excessive uterine bleeding with hypothyroidism, citing a number of authors who have called attention to this fact In these patients excessive uterine bleeding is associated with headache and lassitude, often erroneously attributed to anemia The headache is severe, bursting in character, increasing to throbbing with exertion and unrelieved by the usual analgesics Diethylstilbestrol, in doses of 0 5 mg once or twice a day, *may give relief in an hour or two* The bleeding may be of a flooding nature Deisher believes that trial of thyroid therapy may, in many cases, obviate the necessity for curettage or hysterectomy Thyroid medication is much more acceptable to the patient, much less costly and, when indicated, much more effective than an extended and expensive series of injections of hormone preparations Physical examination reveals no sharply diagnostic features, but the combination of obesity or nervous slenderness with thickened dry skin, dry hair, cracked finger nails, low pulse pressure and, rarely thyroid enlargement substantiates the diagnosis of hypothyroidism Pelvic changes are minimal, consisting only of some tenderness of the adnexal tissues Pathological examination of the endometrium reveals normal or slightly hyperplastic architecture, with no obvious reason for the increase in bleeding The author cites five illustrative cases

Nature of Intrinsic Factor of Castle.—Hall says that vitamin B_{12} parenterally administered, is as effective in the treatment of pernicious anemia as extracts of liver. However, when administered by mouth, it requires, for its effective utilization the presence of a potentiating agent. In the absence of such an agent, the hematopoietic responses to the oral administration of vitamin B_{12}, in doses up to 100 times the minimal effective parenteral dose, are variable and unpredictable. Potentiation may be provided by known sources of intrinsic factor, such as gastric juice of normal or elevated acidity from human beings and extracts of the stomach and intestines of swine. Concentrated preparations that yield consistently effective and reliable therapeutic results have not yet been produced, owing to the ready destructibility of the intrinsic factor and the consequent loss of a portion or all of the intrinsic factor activity during the process of concentrating gastric or duodenal substances. Studies supporting the concept that the intrinsic factor is of the nature of an enzyme are described.

*Aureomycin and Chloromycetin in Treatment of Experimental Plague. S. S. Sokhey and M. K. Habbu.—p. 197.

Aureomycin and Chloramphenicol in Plague.—Sokhey and Habbu believe that results obtained in their standardized experiments on mice should parallel those of clinical trials. To put a drug to the severest test, the authors started its administration after septicemia had developed, which was 72 hours after the induction of infection. Antiplague serum, a number of sulfonamides, penicillin and streptomycin had been tested previously for their efficacy in the therapy of plague. Aureomycin in a dose of 1 mg. every three hours for the first 12 hours and then every six hours for the rest of the 10 days, i. e., 42 mg. in all, was sufficient to save nine animals out of 10 infected with plague. When the dose of aureomycin was doubled, it still had to be administered for at least seven days for the same results to be obtained. Chloramphenicol, 8 mg. every three hours for the first 12 hours and then every six hours for the rest of the 10 days, i. e., a total of 336 mg., was necessary to obtain the same result. If these drugs were not given in sufficient quantity and for a sufficient number of days, infection recurred and killed some animals even as long as 15 days after the administration of the drug was stopped. These experiments show that both aureomycin and chloramphenicol given by mouth were effective in the treatment of plague.

Hypothyroidism and Reproduction.—Krohn and White say that there are many indications that hypothyroidism is associated with inadequate reproductive function. Myxedematous women, for example, often suffer from menstrual disturbances and seldom conceive and bear children. Experimental analysis of the relation between the thyroid and ovary has not, however, led to clearcut conclusions. The effects of hypothyroid conditions on the reproductive processes of the female albino rat were therefore studied afresh, and the results of thyroidectomy and of chemical suppression of the thyroid compared. Some observations were made also on the rate of development of the litters from the treated rats. The authors found that pharmacologic suppression was more effective in causing a consistent depression of the metabolic rate than was surgical ablation of the thyroid. The estrous cycle tended to be longer, especially in thyroidectomized animals, and more variable in length. Hypothyroid animals ovulated and conceived, but fewer young were brought to term than in a previous normal pregnancy, due to resorption of fetuses at varying stages of gestation. The young of rats receiving thyroid-suppressing drugs all died by the end of the fourth week after birth, but the young from thyroidectomized mothers developed normally. It is suggested that the young of animals who had been injected died because suppression of the fetal thyroid by thyroid-depressing drugs which passed from the mother both before and after birth prevented normal development. It is not yet clear whether the interference with reproduction caused by hypothyroidism can be explained adequately by a general slowing down of cellular activity or whether any specific hormonal mechanism is primarily involved.

Patent Ductus Arteriosus.—Karnell and his associates discuss the various roentgenologic methods for the diagnosis of patent ductus arteriosus. The angiocardiographic method had been in use for about 10 years, but no one had succeeded in visualizing the ductus directly, and the indirect signs proved to be more or less unreliable. Castellanos' method, using countercurrent injection of opaque substance into the brachial artery, was not suitable for routine purposes. The authors were able to make a diagnosis in some cases of patent ductus arteriosus by means of thoracic aortography. This method can be used in adults, is more difficult in children, and in infants almost impossible. If the ductus is wide, it is possible to maneuver a catheter inserted in the pulmonary artery through the ductus into the aorta. This is the most direct way of establishing the presence of a patent ductus. It does not involve any new and troublesome manipulation for the patient. The heart must be catheterized anyway, and when the catheter is in the pulmonary artery an attempt can be made to push it farther through a patent ductus. If there is no success after a few minutes, the attempt should be given up. Unless a ductus is found almost at once, the chances are that none is present or that it is not wide enough for catheterization. The authors used catheterization in 10 cases of patent ductus, and they were able to push the catheter through the ductus in four of these. Since patent ductus is not a rare defect and since catheterization must have been done in many such cases, the authors assume that they were probably not the first to insert the catheter through the ductus. They find it surprising that no one has called attention to the diagnostic value of this procedure.

Hodgkin's Disease and Pregnancy.—At the Radiological Clinic in Aarhus, Denmark, Bichel observed the course of Hodgkin's disease in 81 women, 11 of whom became pregnant. The literature contained rather detailed reports of 46 women in whom Hodgkin's disease was complicated by pregnancy. Thus it was possible to study 57 cases in which a total of 65 pregnancies occurred in the course of Hodgkin's disease. Of the 65 pregnancies, 42 were carried to term. A larger number of observations is necessary before the influence of pregnancy on Hodgkin's disease, and vice versa, will be clear but on the basis of the observations so far obtained, the author feels justified in concluding that conception frequently occurs in women with Hodgkin's disease, that from an obstetric point of view the pregnancy, parturition and puerperium run a normal course in the great majority, and that acute exacerbation of the disease is not more frequent during pregnancy than could be expected without it. Only one case is on record in which the mother died during pregnancy. Only one case has been reported in which it can be said with a reasonable degree of certainty that intrauterine transmission from mother to child took place. Generally, there will be no indication for interruption of pregnancy in patients with Hodgkin's.

*Considerations on Modern Treatment of Tuberculous Meningitis of Adults. P. Sédallian, R. Maral and C. Exbrayat.—p. 643.
Permeability of Meninges in Course of Meningitis, Particularly in Tuberculous Meningitis. P. Sédallian, R. Maral, J. Traeger and G. Aventurier.—p. 673.

Chloramphenicol in Typhoid.—Sédallian treated 119 patients, 85 adults and 34 children, who had typhoid with chloramphenicol (chloromycetin®). The author regards an initial massive dose as useless and even dangerous. It could have been partly responsible for the fatal cardiovascular collapse which took place in six patients 18 hours to three days after the dose was given. A dose of 50 to 60 mg. per kilogram of body weight should be given by mouth every four hours for 15 days. Treatment should be continued with a dose of 25 to 30 mg. per kilogram of body weight for at least five additional days in cases in which cultures of feces remain positive. The patient is to remain in bed for one week after discontinuation of the drug. He may be discharged from the hospital one week later. Recovery resulted in 95 per cent of the patients. Temperature became normal gradually in 65 per cent of the patients and by a sudden drop within 24 hours in 30 per cent. Defervescence occurred in two stages with intervening fever in 5 per cent of the patients, most of them children. A mild rise in temperature recurred between the tenth and twentieth days in 20 per cent. Headache subsided rapidly, but insomnia disappeared only after the temperature became normal. Diarrhea continued occasionally for eight to 10 days after discontinuation of the drug. Diminution of the size of the spleen was observed usually at the time of or soon after the temperature became normal. Chloramphenicol probably prevents the ocurrence of new intestinal ulcers, but it does not hasten the healing of ulcers. Only two patients had intestinal hemorrhages. Intestinal perforation and phlebitis were not observed. The course of the disease was shortened and convalescence was hastened. Twenty patients had recurrences but responded well when treatment was resumed. Only early and prolonged treatment will reduce the high incidence of relapses. Chloramphenicol seemed to be ineffective in bacilli carriers. Although chloramphenicol is a highly valuable drug, prophylactic treatment with typhoid vaccine should not be neglected.

Modern Treatment of Tuberculous Meningitis.—Sédallian and co-workers report on 173 patients over 14 years of age with tuberculous meningitis who were admitted to the hospital during the period of May 1947 to October 1949. Of the 173 patients, 132 were admitted before Aug. 1, 1948, and 17 of them are living. Forty-one were admitted after Aug. 1, 1948, and 17 of them survived and are in a state of clinical recovery. Comparison of these two groups shows in a general way the progress made. The patients admitted after Aug. 1, 1948, were in a less serious condition because diagnosis had been made earlier. Methods of treatment had been improved. Mildly abnormal cerebrospinal fluid during or after treatment for miliary tuberculosis suggests a caseating meningitis in an early stage and requires treatment. Transitory meningitic episodes associated with tuberculous nonmiliary primary infection may regress spontaneously within a few days. Except for rare cases, combined treatment by intramuscular and intraspinal route should be instituted in all cases in which the diagnosis of tuberculous meningitis has been established. Streptomycin, para-aminosalicylic acid and glucosulfone sodium (promin®) and its derivatives were the drugs employed. A few patients made a rapid recovery, with cerebrospinal fluid restored to nearly normal after 25 days of treatment. Treatment by intramuscular route was discontinued on the hundred and fifty-fifth day, and recovery was maintained for 21 months after discontinuation of the drug. The majority of the patients showed definite improvement in the cerebrospinal fluid in the course of the fourth or fifth month of treatment, which in general was discontinued after the fifth or sixth month, when the cerebrospinal fluid was restored to nearly normal. Two patients showed late improvement and were in a confusional state for four months. They made a satisfactory clinical recovery after eight months of treatment, and the recovery was maintained for 23 and 16 months, respectively, after treatment was discontinued. Two patients had a recurrence but recovered when treatment was resumed. One late fatal recurrence was observed one year after the first course of treatment was terminated. Clinical recovery usually occurred much earlier than the restoration of the cerebrospinal fluid to normal, the latter requiring seven to 10 months. Follow-up examinations should be made every two weeks for two months following discharge from the hospital. One monthly examination is advisable for the next six months and several additional examinations every second or third month, making a total follow-up period of 18 months.

*Bone Changes in Leukemia in Children. J. Hasbun and R. Eberhard.—p. 289.
Tuberculoma of Brain in Infants. Z. Fuentes A.—p. 298.

Bone Changes in Leukemia.—Hasbun and Eberhard report nine cases of acute lymphatic leukemia in children in whom the diagnosis was facilitated by periodic roentgen examination of the bones. Bone lesions visible in the roentgenograms are frequent in acute lymphatic leukemia of children. Lesions in eight cases were located in the distal metaphysis of the femur and in the distal ends of the radius and the ulna in one case. The roentgen picture was of the osteolytic type in five cases and of the osteochondrotrous subperiosteal and osteosclerotic types in the other four cases. Osteomyelitis is differentiated from acute lymphatic leukemia, in patients who present bone lesions and local pain, by examination of the blood and the bone marrow obtained by sternal puncture.

Injection of Chemotherapeutics into Pulmonary Cavities.—Ebers employed intracavitary injections in six children and adolescents. He believes that intravenous injection of chemotherapeutics can be tried in cases of cavitary tuberculosis in which the pleural cavity is obliterated and in which extent and toxicity of the tuberculous process make other therapeutic measures inadvisable. The intracavitary injection can be given either in preparation for a surgical intervention or as a last resort. There are cavities which, because of their proximity to large pulmonary vessels, do not permit intracavernous injection. The choice of the site of injection, whether at the front or back of the thorax, is determined by tomographic examination; that is, the shortest distance is taken. The injection is made with the patient on the tilted x-ray table. The patient is placed so that the cavity is struck by the central beam. The injection is made with a syringe which has a cannula 8 to 10 cm. in length. When the intercostal space has been entered, a roentgenologic control is made to check the direction of the cannula, which is then pushed forward while air bubbles or secretion are aspirated. Penetration of the wall of the cavity can sometimes be felt. The patient should rest in bed for a day after the injection. At first, injections are made two or three times and later once weekly. The authors used a 2 per cent suspension of 4-acetylaminobenzaldehyde thiosemicarbazone (conteben® or Tb 1-698) in distilled water, a 2 per cent suspension of the same substance in a 4 per cent solution of paraaminosalicylic acid, a 4 per cent solution of paraaminosalicylic acid without the addition of the thiosemicarbazone preparation, a 10 per cent solution of streptomycin or a soluble derivative of the aforementioned thiosemicarbazone. The quantity injected was 2 to 4 cc. The early results were better than any with any other method. Continuation of these therapeutic experiments is therefore advisable, although the method is not without danger.

*New Possibilities of Salicylic Acid Therapy: Intravenous Therapy with Solusal® (Ethanolamine Salt of Salicylic Acid). W. Blumencron and E. Borkenstein.—p. 449.

New Possibilities of Salicylic Acid Therapy.—According to Blumencron and Borkenstein, the intravenous route for administration of salicylic acid is superior to any other with respect to rapidity and duration of effect on true rheumatism. It is the method of choice in recurrences, in which oral administration has lost its efficacy because of habituation to the drug. The prompt effect of intravenous administration is the result of the thrustlike production of a high salicylic acid concentration in the blood. A higher salicylic acid concentration in the blood may be obtained with ethanolamine salt of salicylic acid (solusal®) administered intravenously than with sodium salicylate. This higher concentration of the drug may be maintained for at least 10 hours by a repeated injection of solusal.® The average blood serum value was 26 mg. per 100 cc. five hours after the injection of 10 cc. of 20 per cent solusal,® while it was 10.5 mg. per 100 cc. after the injection of 20 cc. of 10 per cent sodium salicylate. The maximum salicylic acid effect may thus be obtained by this route with much smaller doses than by any other route. Untoward reactions to salicylic acid are avoided. There was not a single instance of albuminuria, so that intravenous salicylic acid therapy may be practiced even in the presence of renal lesions. Intravenous administration was well tolerated by patients in whom administration of small doses by mouth was not feasible because of intolerance. Intravenous injections of solusal® were well tolerated by highly sensitive patients, provided they were made slowly and provided the contents of the syringe were mixed with the patient's blood. The rapid effect of the intravenous salicylic acid injection on the symptoms of true rheumatism makes it possible to use it as an aid in differential diagnosis of true rheumatism from other types of rheumatism. Only an analgesic effect may be expected from salicylic acid preparations in focal forms of rheumatism and in rheumatoid forms, but it may be more pronounced in intravenous than in oral administration of the drug.

100:469-492 (July 22) 1950. Partial Index

Causes of Immediate and Late Failure of Surgical Intervention on Stomach for Ulcer and Its Complications. H. Finsterer.—p. 472.
*Preliminary Results of Vagotomy for Peptic Jejunal Ulcer (Recurrent Ulcer). F. Mandl.—p. 476.
Rheosphygmography, New Method for Diagnosis of Peripheral Vascular Diseases. H. Jantsch.—p. 478.

Vagotomy for Peptic Jejunal Ulcer.—Mandl performed vagotomy on 15 patients with an ulcer recurring after gastrectomy. In three of these patients, 19 to 28 years had elapsed since the gastrectomy. One of the 15 patients died from a suppurative meningitis on the tenth day after the vagotomy. Only one month had elapsed since the vagotomy was performed in another patient, and the follow-up period was, therefore, too short to permit definite conclusions. Complete recovery resulted from vagotomy in six patients. Two patients were therapeutic failures. One patient made an uneventful recovery but died from uremia three months after the vagotomy; his case is considered as doubtful. Evaluation of results is not easy in the four remaining cases. One patient had been operated on four times for peptic jejunal ulcer which was considered as surgically incurable; vagotomy was performed, but only temporary improvement resulted. Carcinoma simulating a recurrent jejunal ulcer 19 years after gastrectomy was revealed by necropsy nine months after the vagotomy in one case. Vagotomy was incomplete because detection of the posterior branch of the vagus was impossible in one case with gastrocolic fistula. Death resulted from severe hypoproteinemia in spite of vagotomy in one patient. Vagotomy offers many advantages as compared to radical methods in clear cases of peptic jejunal ulcer.

BOOK NOTICES

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association with the Comments That Have Appeared in The Journal of the American Medical Association, 1949. Cloth. $2. Pp. 231. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal [n.d.].

Of the six excellent reports on the status of various therapeutic preparations and procedures contained in this volume, perhaps the most noteworthy is the progress report "Estrogens and Androgens in Mammary Cancer," which presents an admirably organized study of the problem, and which is to be continued with procedures revised in the light of experience. The present conclusion is that steroid hormones represent a new weapon for the palliative treatment of breast cancer, to be used in those cases in which surgical or irradiation treatment, or both, cannot be applied or have proved unsuccessful. The other reports in this category are equally well planned and informative. That on organomercurial compounds represents a continuation of the Council's effort to encourage the development of more objective evidence concerning the true value of this class of compounds. The report of Grimson and co-workers, "Newer Adrenolytic, Sympatholytic and Ganglionic Blocking Drugs," is a brief but careful evaluation of several agents for use as substitutes for regional sympathetic block or actual sympathectomy in peripheral vascular disease problems.

The three papers "Aluminum in the Therapy and Prophylaxis of Silicosis," "Status Report on Analeptics" and "New Analgesics" emphasize methods and procedures for investigation and evaluation and are thus related to the Luykx paper, "Progress Without Statistics," and the two sponsored by the Council's Committee on Research, "Methods of Clinical Study and Evaluation of Therapeutic Agents in Poliomyelitis," and "Fundamental Scientific Research Essential to Progress in Applied Therapeutics." Together, these form an illuminating and instructive commentary on the methods and procedures of modern therapeutic research. Certainly they evidence the Council's increasing preoccupation with this field.

The report consigning sulfathiazole and sulfathiazole sodium to the therapeutic discard, one rejecting a pseudoscientific anti-obesity preparation, Pit-thyrocas, and the mention of a long list of cancer "cures" in the report "Cancer and the Need for Facts," alone represent the type of condemnatory report that in other years formed so large a part of the collected reports. Eight reports on adoption of protected and generic names for drugs, the report of the Council's annual meeting, some instructive comments on the Council's rules and a statement on the legal requirements for prescription writing round out the contents of this small but extremely valuable book.

New and Nonofficial Remedies, Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1950. Issued under the Direction and Supervision of The Council of Pharmacy and Chemistry, American Medical Association. Cloth. $3. Pp. 800. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1950.

Though it seems somewhat irreverent to apply the overworked term streamlined to such an authoritative and dignified volume, the dark blue cover with gold lettering and the lines of the 1950 edition, together with the new typeface employed, immediately suggest the word. This characteristic of the cover is carried out in the editorial attention that has obviously been given to the text. Comparison with the 1949 volume will show that an attempt has been made to eliminate repetitious and unnecessary phraseology and to achieve more logical arrangement of material (for example, that in the vitamin chapter), in effect, to give the book a more homogeneous character. Still further effort in this direction might be desirable. A new and significant section has been added: a list of trade names recognized by the Council for pharmacopeial preparations which are now excluded from the book by the rule that products of 20 years' official standing are not accepted for consideration. The continued operation of this rule gives additional verisimilitude to the words "new" and "nonofficial" in the title. The relegation of tests and standards for accepted nonofficial preparations to a separate section is continued. This section has been made more readable by the change to a clearer type.

About 58 new preparations have been added, including antihistaminics, sulfonamide mixtures, antibiotics, a water-soluble vitamin A, and vitamin B_{12}. Many of these stand accepted under protected names and appear under the recognized generic designations. There has been no radical revision of the text, but several chapters, including that on the vitamins already referred to, have been judiciously rearranged in the interest of clarity and accessibility of the material. Notable among these are the chapter on hormones and synthetic substitutes and the two chapters on anti-infectives.

Communicable Diseases. Edited by Roscoe L. Pullen, A.B., M.D., F.A.C.P., *Professor of Graduate Medicine, School of Medicine, Tulane University of Louisiana, New Orleans.* Cloth. $20. Pp. 1035, with 273 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1950.

It is an interesting commentary on medical writing that for many years there has been a crying need for a comprehensive monograph on infectious disease in spite of the fact that during the past two decades the practical advances in this field have probably been greater than in any other branch of clinical medicine. Medical students and physicians have had to rely on textbooks of general medicine and of bacteriology and immunology, current medical periodicals, and specialized monographs dealing with chemotherapy and with single infections, in order to keep abreast of advances which have literally revolutionized the management of many communicable diseases. The volume is designed to cover the entire field of contagious illness. Its 60 chapters were written by 53 authors, 39 of whom are either active or former faculty members of the Tulane and Louisiana State Medical Schools in New Orleans. Discussion of the individual diseases is presented in an orderly manner, the classification used being based on the predominant clinical manifestation caused by the infection, i. e., involvement of skin, respiratory tract and nervous system. There are numerous instructive illustrations, tables and charts, and most of the chapters include rather comprehensive bibliographies.

The subject matter covered is almost entirely clinical, and the text is for the most part descriptive. Herein lies the most serious defect in the monograph. No branch of clinical medicine can today be adequately taught to undergraduate or postgraduate students without a strong emphasis on pathological physiology. Many of the chapters fail to touch on mechanisms of pathogenesis, recovery and prophylaxis, discussions of which would greatly increase the reader's understanding of each of the diseases described. To be sure, the recently published companion volumes of Dubos and Rivers dealing with bacterial and viral infections present the mechanistic approach to microbial disease, but these are essentially textbooks of microbiology rather than of clinical medicine. For the clinician to appreciate the true nature of any infection and the rationale of its management, he must have a clear understanding of both the behavior of the invading parasite and the defense mechanisms of the host. If in future editions discussions of these important matters, which by too many clinicians are considered of only theoretical interest, can be added to the otherwise excellent text, the over-all value of the monograph will be greatly increased. In its present form this comprehensive volume is certain to serve a most useful purpose and will undoubtedly be widely read not only by medical students but also by practicing physicians.

A Textbook of Histology: Functional Significance of Cells and Intercellular Substances. By E. V. Cowdry, Professor of Anatomy, The School of Medicine, Washington University, St. Louis, Mo. Fourth edition. Cloth. $8.50. Pp. 640, with 337 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1950.

Again thoroughly revised, the present edition of this work is considerably expanded beyond the third edition (1944). The first two editions were written for keener, more mature students and studiously avoided illustration or discussion of what becomes evident in the laboratory. The streamlining of factual content that took place in the third edition has been maintained, but the text has been expanded by additional use of comparative tables and elementary introductory remarks. There are many new references and some new figures. The thoroughness of each of the three revisions, with attendant fluctuations in volume, has not diminished the distinctive character of Cowdry's text. The treatment remains a personalized, highly selective account of the major aspects of histology, with some topics, notably skin and blood, selected for emphasis. The vitality of presentation is matched only in earlier editions. Current research activity is pointed up by references to illustrations in "Life" magazine and admonitions to watch for the publications of particular authors. The frankly partisan presentation of existing controversies is possibly a desirable stimulant to the critical student.

It is clear what Cowdry thinks a course in histology should be and also what attitude should, according to him, be cultivated in the student. These opinions require thoughtful consideration by both instructor and student. For the instructor who agrees with this emphasis and approach, this edition is a distinct advance. Where lectures are designed to deal amply with other aspects of histology, the book provides interesting auxiliary material. The text assumes laboratory familiarity with human material and with some fresh preparations. A set of questions on each chapter is included. The book is thus geared to integration in the medical curriculum as a prime objective rather than to function as an authoritative reference on minutiae.

Pye's Surgical Handicraft: A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of Surgical Dressers, House Surgeons and Practitioners. Edited by Hamilton Bailey, F.R.C.S., Surgeon, and Surgeon-in-Charge of the Genito-Urinary Department, Royal Northern Hospital, London. Sixteenth edition. Cloth. $6. Pp. 724, with 830 illustrations. The Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1950.

This edition of this popular surgical handbook has been rewritten with emphasis on standard surgical principles and technics. The concise paragraphs and numerous illustrations explain fundamental principles of handling of common surgical problems. First aid is emphasized, technics for emergency and minor surgery are outlined, and there is a description of available instruments and the standard use of bandages and casts. Though not a reference textbook on surgery, this handbook is a practical and detailed outline which should aid medical students and general practitioners. It should also afford interesting reading for those with more detailed surgical experience. The content of the book is appropriately described by its title, "Surgical handicraft," and the book is recommended to those desiring information on simple and standard general surgical technics.

Techniques in British Surgery. Edited by Rodney Maingot, F.R.C.S. Cloth. $15. Pp. 733, with 473 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1950.

This work represents a compilation of articles by 29 British surgeons, each of whom is an authority in his field. While the title may suggest that surgical technics are different in Britain, this is not the case. Surgical procedure today in Britain is not different from that practised in the United States, or, for that matter, anywhere else.

The arrangement of the material is not well balanced. The space devoted to orthopedic procedures greatly overbalances such timely subjects as surgery of the gastrointestinal tract. It seems that in a one volume work, a chapter on so highly specialized a subject as mammaplasty, to which 15 pages are devoted, is obviously a superfluity. The section on the surgical treatment of pulmonary tuberculosis is timely and well written. It is felt that the term "incautious" should be discarded from a surgical textbook, for caution is the keynote of all surgery (page 291, figure 179). The section on acute infections of the hand is well written but, here again, too abbreviated. A better correlation of subject matter would be desirable. For example, article 13 deals with benign strictures of the rectum and is followed by cysts of the epididymis, which precedes a chapter on carcinoma of the head of the pancreas only to be followed by an article on some surgical aspects of gastric surgery, which is succeeded by an article on hypospadias, and, immediately after this, an article on aseptic intestinal anastomosis. Among others, some of the outstanding articles in this compilation are on the surgery of the thyroid gland and the procedures relating to thoracic surgery. Some of the illustrations are excellent; others are too diagrammatic.

Types of Diabetes Mellitus and Their Treatment. By Arthur R. Colwell, M.D., Associate Professor of Medicine and Director of Medical Specialty Training, Northwestern University Medical School, Chicago. Publication Number 67, American Lecture Series, A Monograph in American Lectures in Endocrinology. Edited by Willard O. Thompson, M.D., Clinical Professor of Medicine, University of Illinois College of Medicine, Chicago. Cloth. $2.25. Pp. 97, with 6 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W. Toronto 2B, 1950.

The author is one of the best qualified students of clinical diabetes in the United States and presents material for the general clinical reader in well chosen language, appropriately condensed for quick perusal and based at all times on clinical rather than theoretical considerations. This volume is a handbook for quick reference for the physician who does not see many patients with diabetes but who wants to know how to take care of his diabetics in the most thoroughgoing and safe way. The point of view is not limited to any one of the several types of dietary treatment of diabetes nor does the author show any favoritism for a particular type of insulin. Although this is in no sense a manual for the mutual use of physician and patient, sufficient information is included herein so that a physician can provide for a patient, in typed or mimeographed form, essential information about foods and other problems of the diabetic, for the management of any of the ordinary cases of diabetes encountered in clinical practice. It is important to note that the directions for the safe and thoroughgoing management of emergencies, including coma, infections and surgical operations are based on the time-tested practical scheme devised by Dr. R. T. Woodyatt. In a field where the clinical and experimental literature is so voluminous, the author has made a selection of 50 bibliographic references, which will be of real value to the clinical reader who wants to be abreast of the important recent publications. This book can be recommended confidently to any physician who wants a condensed and simple manual for the treatment of diabetes.

Plastic and Reconstructive Surgery: A Manual of Management. By Ferris Smith, M.D., F.A.C.S., Consultant in Plastic Surgery, Blodgett Memorial Hospital, Grand Rapids, Michigan. Cloth. $15. Pp. 895, with 592 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1950.

The purpose of this book is to present and emphasize the trend of plastic surgery since World War I. The basic principles of plastic surgery are discussed, and methods of application are evaluated. The author states in his preface that such conditions as hypospadias and epispadias should be corrected by the urologic surgeon, absence of the vaginal tract by the gynecologist and lesions of the tendons, nerves and bones by the orthopedist.

The first chapter, which contains general considerations, is particularly well presented. More space could have been devoted to the section pertaining to plastic and reconstructive surgery of the breast. Although this subject was well presented in the eight pages devoted to it, the operative procedures should have been presented in the form of illustrations along with the preoperative and postoperative photographs shown. The book is well written and well printed. Numerous preoperative and postoperative photographs are shown, and these are always convincing. This will make an excellent reference book for those interested in plastic and reconstructive surgery.

Surgery of Cataract. By Daniel B. Kirby, A.M., M.D., LL.D., Professor of Ophthalmology, College of Medicine, New York University, New York. *Cloth. $30. Pp. 695, with 339 illustrations. J. B. Lippincott Company,* 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1950.

This masterful treatise is the most comprehensive work of this kind ever to appear. It is so ample that at times it is almost repetitious. In a wide exploration of the literature of cataract surgery, there are numerous extensive direct quotations, not always readily distinguishable from the author's original material. One wonders whether a greater purpose would not have been served by less verbiage so that the book might be sold in a price range with a wider appeal, especially to the beginning ophthalmic surgeon for whom a study of this work would be most beneficial. Binding, printing and the numerous illustrations, many of them in color, are of the highest caliber.

There is assembled a complete account of the history of the cataract operation as far as it is known for the past 3,000 years, with a detailed description of the early couching operation and the evolutional process involved in the development of the modern methods employed. Further chapters deal with the basic subjects of embryology, anatomy, physiology and pathology of the lens and asepsis and antisepsis. Instruments are described in detail, especially those favored by the author. In the drama of cataract surgery, the author brings a touch of philosophy and theology into the discussion of the training and preparation of the eye surgeon. Consideration is given to the importance of the preoperative examination of the patient and to the standards for judging progress or arrest of lens opacities. In a review *of the nonsurgical treatment of cataract, there is emphasized* the lack of results from all known methods of this type of treatment.

The etiology and classification of cataracts are considered at length and indications given for extracapsular and intracapsular extractions, with the latter favored in most instances. This is quite in keeping with present trends, and, while all accepted technics are described, the detailed steps and procedures developed by the author and published in numerous previous articles are systematically emphasized. Most eye surgeons develop the practices learned from a variety of sources which best fit their particular capability and temperament. There can be no doubt that Dr. Kirby's technic is highly satisfactory, and whether or not the reader decides to adopt the method in toto he will find concretely expressed many ideas which may be applied and adapted to personal needs. The chapter on the prevention and handling of complications is particularly practical. The chapter on the correction of aphakia is particularly valuable, since this phase has received a minimum of attention in the past, with the drama of the surgical procedure completely overshadowing the necessity of proper optical correction of the defect resulting from loss of the lens.

It is likely to be a long time before any book on the surgical aspects of the cataract operation approaches the volume of material in this monumental compilation, and while the cost will deter many from owning the volume those with extensive interest in the subject will give it an important place in their libraries.

Personality in Peptic Ulcer. By Albert J. Sullivan, M.D., Head of Section on Gastroenterology, Ochsner Clinic, Tulane University of Louisiana School of Medicine, New Orleans, and Thomas E. McKell, M.D., Instructor in Medicine, Tulane University of Louisiana School of Medicine, New Orleans. Cloth. $3. Pp. 100, with 13 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This is an interestingly and convincingly written little book indicating that intrinsic (personality) psychic factors and extrinsic psychological factors (emotional situations) serve as predisposing and excitatory causes of peptic ulcer. Data and cases are presented, and the role of psychotherapy is pointed out. The authors properly emphasize "that adequate treatment depends upon proper evaluation of the numerous etiologic factors involved in the production of each individual case of peptic ulcer." In view of the title, the saneness of the book is refreshing. The book will be helpful to those who desire a good orientation toward the role that personality and emotional factors play in so-called psychosomatic disorders.

Physician's Handbook. By Marcus A. Krupp, M.D., Assistant Clinical Professor of Medicine, Stanford University School of Medicine, San Francisco, *Norman J. Sweet, M.D., Assistant Professor of Medicine,* University of California School of Medicine, San Francisco, Ernest Jawetz, Ph.D., M.D., Associate Professor of Bacteriology, University of California School of Medicine, San Francisco, and Charles D. Armstrong, M.D., Clinical Instructor in Medicine, Stanford University School of Medicine, San Francisco. Sixth edition. Boards. $2.50. Pp. 380, with illustrations. University Medical Publishers, Post Office Box 761, Palo Alto, California, 1950.

It is amazing how many facts the authors have been able to compress into this small book. It is in a sense a counterpart for medicine to the well known "Handbook of Chemistry and Physics," and is similarly encyclopedic in its coverage. The first chapters are on general and specialized types of physical examinations. One is reminded, for example, how to test the fifth cranial nerve, or one may find a table showing the *normal range of motion in ulnar deviation of the wrist. Then* follow chapters on roentgen examinations, electrocardiography and special procedures in various specialties. The next sections are largely concerned with therapy; here, technics of treatment are described and a list of drugs and dosages given. Finally, most of the remainder of the book is concerned with laboratory technics, which are most simply and usefully stated.

No student or physician can ever remember all the facts he needs nor even their interpretations. This handbook will almost surely give him details of any procedure he is looking for or may even suggest a procedure to him, with a two-line explanation of what it means. Although there is now no dearth of pocket handbooks of medicine, this is certainly one of the best and will please any user. Criticisms are hard to make, for the content and format are both excellent. One might wish for an occasional credit line, but it is characteristic of most handbook material that the popularity of the context soon hides its origin.

Soviet Psychiatry. By Joseph Wortis, M.D., Assistant Clinical Professor of Psychiatry, New York University College of Medicine, Brooklyn. Cloth. $5. Pp. 314. The Williams & Wilkins Company, Mt. Royal & Guilford Aves., Baltimore 2, 1950.

This monumental work of Dr. Wortis is based on about 7,000 items from the Russian neuropsychiatric and political literature covering a period of over three decades. The author wisely devotes the first chapter of his book to a careful discussion of the ideology of Soviet Russia. Against this background, he focuses the materialistic and practical bent of Russian scientific thinking as contrasted with the philosophical idealism of the West.

The cornerstone of the materialistic orientation is that "mind is a function of matter and derivative from and secondary to it." Soviet psychiatry is, therefore, organically oriented with pavlovian physiology as the nucleus and cannot accept the concept of the unconscious, which is the foundation of freudian psychology. Wortis devotes an entire chapter to a discussion of Pavlov's ideas of excitation and inhibition and the physiological explanation of mental disease.

The chapter on the organization of psychiatric care is extremely interesting. Russia, with a population of 200,000,000, has only one-half the number of psychiatrists and only one-tenth the number of psychiatric beds as compared with the United States. The Russian setup is so different from that of the United States that it warrants further study.

From the chapter dealing with psychoanalysis and psychotherapy, it appears that psychoanalysis has no place in the Soviet scheme of things. Psychotherapy rests primarily on "common sense" treatment combined with a strong emphasis on work and social activities. The Russians have made a religion out of work, and the psychiatrists use it extensively as a therapeutic agent. The child in the Soviet Union is considered the "flower of the nation," and the care and attention it receives from infancy through school may, in a sense, be regarded by some as prophylactic psychiatry. A chapter is devoted to this subject in which the author points out the close integration of Soviet psychology with pedagogy, based on the thesis that it is possible "to alter character and personality development by training, pedagogy and social influence."

The chapter on treatment refers to the use of such standard methods as sleep treatment with amobarbital sodium, insulin therapy (the Russians reported on a study of over 100 cases as long ago as 1936), pentylenetetrazole (metrazol®), electroshock, as well as some novel procedures which include the Bogomolets antireticular cytotoxic serum, colloidoclastic shock, autogenous serum and roentgen irradiation treatment.

The reader is urged not to skip the appendix, wherein there is reference to devastating criticism levelled against one of the preeminent Russian psychologists, Rubinstein (the author of "Foundations of General Psychology"), by one of his countrymen for his attempt to effect a synthesis between the conscious and the "freudian unconscious." In the specter of classless existence where the person does not count as a unit but as a part of the whole, the work and the accomplishments of the whole are predominantly important and color the person only in passing. It is not at all unlikely that the psychologist Rubinstein may, in a subsequent edition, alter his views to conform more strongly to marxism and still remain scientifically honest.

The over-all feeling one has, after putting the book aside, is that Soviet psychiatry is a healthy, progressive discipline and that the author has clearly defined the forces responsible for the organic orientation as well as for the total eclipse of psychoanalysis there. It is commendable that Wortis, to provide a real and comprehensive survey of the state of psychiatry in Russia, has gone to the trouble of learning and mastering the language so that he might be able to read and translate the Russian neuropsychiatric literature, which he has approached in a spirit of friendly objectivity. It is unfortunate that the mass hysteria engendered by political friction because of different ideologies encompasses the field of science and the exchange of ideas and that the publishers of this excellent book have thought it expedient to justify its publication. It is regrettable that the times are such that one must say that courage was required to write such a book.

Those who know the language, who have visited the hospitals and talked to some of the leading psychiatrists referred to in the book, can attest that Wortis's presentation is accurate. One must admire the industry of a man who had the patience and zeal to condense the literature of a generation in so prolific a field as neuropsychiatry into so useful a book

In Defense of Mothers: How to Bring up Children in Spite of the More Zealous Psychologists. By Leo Kanner, M.D , Associate Professor of Psychiatry, The Johns Hopkins University, Baltimore Second printing. Cloth. $3. Pp. 167, with decorations by Kurt Wiese. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave , Springfield, Ill., 1950.

It was to be expected that a book such as this would make its appearance, in view of the deluge of "scientific" advice and instruction on raising children that has overwhelmed parents, and especially mothers, in the last few years. Perhaps it is even overdue, but in any event it will be welcomed by physicians, who are so often caught in the difficult position of being obliged to admit that psychiatry and psychology have definite places in child development and yet recognize that more harm than good can come from overapplication of these. Kanner's background of experience commands respect, and the freshness and matter-of-factness of his approach are sure to have a reassuring effect on the contemporary mothers whom he addresses in the first chapter. Chief theme of the book is that present day mothers have been forced into a status of such uncertainty by zealous psychologists that they are losing all sense of proportion and ordinary common sense. This is illustrated vividly in numerous chapters, among which may be mentioned "the devil on the wall," "prevention which does not prevent," "mother love and smother love," and "the what's-it called sex education." Superstitions are dealt with effectively, the chronic complainers (most of whom are from the ranks of pampered children, Kanner states) and their motivations are indexed, and habits such as thumbsucking are brought once more within the range of parental understanding. In a chapter on the Great God Unconscious, Kanner "exposes" the Oedipus and Electra complexes developed by Freud and offers equally penetrating comments on the ego. Especially well done is a chapter reassuring parents of children who may deviate to a greater or less degree from physical and mental normals. This volume can be recommended unreservedly by physicians to parents seeking a way out of the maze of modern management of children.

Playgrounds: Their Administration and Operation. Prepared for National Recreation Association by George D. Butler. Second edition Cloth. $4. Pp. 459. A. S. Barnes and Company, 101 Fifth Ave, New York 3, 1950.

This is a completely rewritten revision of a volume that has been a basic reference for recreation leaders and a textbook for students in the field since the first edition appeared in 1936 Much new information has been added, including a section on the expanded role of the neighborhood playground, descriptions of modern programs and suggestions on how to meet many diversified playground problems. The book is especially noteworthy for its practicality; it reports promising practices that have grown out of actual use in superior programs. Included are materials on selection, training and organization of the staff, use of areas and facilities, development of seasonal activity programs and public relations and finances. The application of principles of good leadership to playground management is emphasized throughout. Physicians who serve on recreation commissions, school boards or other groups responsible for playground development will find the book of real value. Of special interest is the chapter on health and safety, in which are set forth good general principles for accident prevention, emergency care in case of accident or sudden illness, communicable disease control and sanitation and personal hygiene on the playground

Schistosomiasis in South Central Africa: A Clinico-Pathological Study. By Michael Gelfand, M.D., M.R.C.P. Accepted as the thesis for the Degree of Doctor of Medicine of the University of Cape Town Cloth. 25s. Pp. 239, with 23 illustrations. Published for The Post-Graduate Press by Juta & Co., Ltd., P. O. Box 30, Cape Town; P. 0 Box 1010, Johannesburg, 1950.

This monograph represents a fairly comprehensive review of the clinical aspects, diagnostic features and pathology of schistosomiasis in Africa, due to Schistosoma haematobium and/or S. mansoni. The area involved covers the population of south central Africa and Southern Rhodesia but also includes laborers from Northern Rhodesia, Portuguese Africa and Nyasaland. The monograph is divided into an introductory chapter, which describes the terrain and biologic aspects of schistosomiasis, chapters dealing with incidence figures and detailed chapters dealing with urinary, intestinal and pulmonary schistosomiasis, schistosomiasis of the liver and adnexa, of the central nervous system, of the female genital organs and, finally, a chapter on diagnostic aids.

The author contributes much information, apparently based on his own experience, but not hitherto contained in published material. This is especially true in the chapter dealing with central nervous system schistosomiasis, where he states that involvement of the brain by S. mansoni or S. haematobium occurs with significant frequency. This is contrary to general experience, in that practically all hitherto published material relates schistosomiasis of the brain to S. japonicum. Issue can perhaps be taken with conclusions related to the correlation between cirrhosis and schistosomiasis and the insignificance of pulmonary disease in schistosomiasis. This may be true in Africa. This book is useful particularly to physicians who work in areas where this disease is endemic.

Clinical Orthoptic Procedure: A Reference Book on Clinical Methods of Orthoptics. By William Smith, O. D., Associate Instructor in Optometry and Instructor of Orthoptics and Visual Training Massachusetts School of Optometry, Boston, Massachusetts. Cloth. $8. Pp 393, with 70 illustrations. The C. V. *Mosby Company*, 3207 Washington Blvd., St. Louis 3, 1950.

Orthoptics, the process of training and developing comfortable binocular vision in persons with muscular imbalance and fusional imperfections, has been receiving increased attention in the ophthalmologic world in the past decade. In its broader applications it has been universally accepted, but there remains considerable controversy as to the limits of its practicality and the type of case in which it should be advocated.

This volume deals entirely with the practical clinical use of orthoptics and is of interest to ophthalmologists and orthoptic technicians. The author tends to be overly enthusiastic and is not inclined to be sufficiently critical of the limitations of this form of therapy. Discussion of exact diagnoses is somewhat inadequate, and, while some general material is presented on the various forms of muscular imbalance, emphasis is placed on description of individual cases, their treatment and cure. There is insufficient comment on the relation of refractive errors and the importance of cycloplegic refractions, as is perhaps to be expected from one with an optometric background. No mention is made of atropine in the cure of accommodative spasm, for which orthoptics is recommended instead. There is a short chapter on reading disabilities, most of which are on a psychological rather than an optical basis. There is a rather complete description of all instruments used in orthoptics, which is instructive to those who have been confused by the various names given by the manufacturers, but little attempt is made to make any comparative evaluation. It is doubtful that any conclusion can be drawn from the report of two cases of myopia "arrested" by orthoptics, as the progress of the myopia might have ceased without any such treatment. In any field as new as orthoptics there are, of course, legitimate reasons for variations in technics and for overenthusiastic interpretations, which will in time seek levels of accepted practice. This book is recommended in spite of its defects to anyone with sufficient background for critical evaluation.

Der Film als Experiment und Heilmethode. Von Dr. Jaromir Lhotský. Mit einem Beitrag: Vergleichspunkte zwischen Film und Traum. Von Univ.-Professor Dr. Otto Pötzl. Paper. 30 Austrian schillings; 10 marks; 10 Swiss francs. Pp. 136, with 21 illustrations. Verlag Wilhelm Maudrich, Spitalgasse 1 B, Wien IX, 1950.

Dr. Lhotský first considers the psychology of the motion picture from the standpoint of the motivations, emphathies, symbolisms and fantasies of both the exhibitor and the observer. This discussion, though it strives to be eclectic, is generally slanted toward the constitutional and phenomenologic approaches currently dominant in continental academic circles. Subsequent chapters deal with the use of films as media in character testing, psychiatric diagnosis and criminologic investigations, with or without concurrent data as to simultaneous variations in respiration, pulse, "psychogalvanic reflexes" and other physiological functions. Special types of films are then discussed, together with the technics appropriate to their use in specific fields of investigation. In a final chapter, Pötzl likens the experience of viewing a two-dimensional film to the tridimensional imagery of dreaming or the hallucinations of schizophrenia, without attempting to explore the deeper dynamic and symbolic appeals of plot, imagery, symbolic communication or character identification.

Unfortunately, the book not only neglects or minimizes many of the modern analytic and projective approaches to the field of cinematography but ignores the work of many American contributors, such as Darrow, Lasswell and others. Nevertheless, it is an interesting and valuable summary of the European literature in an important and promising, but hitherto neglected sphere of research.

A Text-Book of X-Ray Diagnosis by British Authors in Four Volumes. Volume IV. Edited by S. Cochrane Shanks, M.D., F.R.C.P., F.F.R., Director, X-Ray Diagnostic Department, University College Hospital, London, and Peter Kerley, M.D., F.R.C.P., F.F.R., Director, X-Ray Department, Westminster Hospital, London. Second edition. Cloth. $15. Pp. 592, with 553 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St, Shaftesbury Ave., London, W.C.2, 1950.

Volume 4 is the first published volume of the second edition of this work. The new material that is available in the ever increasing field encompassed by radiology necessitates a new arrangement of the book into four volumes: (1) the head and neck, (2) the chest, (3) the abdomen and (4) bones and joints. Radiologists everywhere have regarded the work of these British authors as one of the best and more definitive publications on the subject. There is little to criticize about this volume except the positive illustrations. It is to be hoped that in subsequent publications the roentgenographic illustrations will be done with negative halftones. This volume contains essentially the same material as was contained in the chapters on bones and joints in the previous edition, with pertinent additions in the form of text and plates. The publishers are to be congratulated on the excellence of the format and the composition of the book.

Meat and Meat Foods: Processing and Preservation from Meat Plant to Consumer. By Lloyd B. Jensen, Ph.D., Chief Bacteriologist, Swift & Co., Chicago. Cloth. $3.75. Pp. 218, with 3 illustrations. The Ronald Press Company, 15 E. 26th St., New York 10, 1949.

This book is one of the Humanizing Science Series, edited by Jaques Cattell, editor of "American Men of Science." Its language is simple and nontechnical. It is intended for laymen. The procedures used in meat processing are described, starting from the farm and proceeding through the packing plant to the consumer's table. This book will be interesting to such persons as meat inspectors, refrigeration engineers, meat dealers and operators of deep freeze lockers and to anyone who wants to know the story of meat production. The aim of using nontechnical language is achieved quite nicely by the author. A person with no basic knowledge of meat processing will find this book very readable and for the most part understandable. There are, of course, a few instances in which the author fails to explain fully the meaning of some terms, but in such cases the reader with some imagination can discern what the author means.

The first few chapters of the book deal with the basic principles and procedures of processing fresh and cured meats and the effects of bacteria on such meat. The chapters following take up in more detail the processing of the various types and varieties of meats. Each chapter contains a paragraph of background material which gives the reader the stimulus to read about the less interesting present methods. The last three chapters deal primarily with problems concerning the safe use of meat. The author has included an extremely interesting appendix of historical notes on the use of meat as a food. This takes the reader back to the cave man and through medieval times up to present day times. A reference bibliography follows this section. The author has done a fine job of removing the heavy material and presents a book which is accurate in detail and interesting.

Surgical Nursing. By Eldridge L. Eliason, A.B., M.D., Sc.D., Consulting Surgeon, Hospital of the University of Pennsylvania, Philadelphia, L. Kraeer Ferguson, A.B., M.D., F.A.C.S., Professor of Surgery, Graduate School of Medicine of the University of Pennsylvania, Philadelphia, and Lillian A. Sholtis, R.N., B.S., M.S., Assistant Professor of Surgical Nursing, Yale University School of Nursing, New Haven, Conn. Ninth edition. Cloth. $4. Pp. 728, with 336 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1950.

This completely revised edition is written for the student nurse to prepare her academically and clinically for the many situations with which she will be confronted in her professional life. The authors aim to present enough of the symptomatology with its anatomic and physiological background to enable the nurse to grasp intelligently the principles of treatment of surgical diseases and to appreciate the responsibilities in the care of her patient. In this edition, the social, economic and public health aspects of surgical disease are emphasized as well as the nutritional, physical and mental aspects of each illness. These topics demonstrate to the student the many influencing factors in the total consideration of the patient's welfare, which is the ultimate objective of modern nursing care.

The authors have not sacrificed the details of bedside nursing in their expanded discussions of pertinent sociologic factors. On the contrary, this subject itself has been amplified, and added attention has been given to the nurse's responsibilities in setting into motion the process of rehabilitation during the patient's hospitalization. The chapter on antibiotics and chemotherapy has been brought up to date. New approaches in neurosurgery and thoracic surgery and the specialized nursing care demanded in these fields are subjects that have been added. New material on the subjects of surgery of the heart and its great vessels, surgery of the sympathetic nervous system in the treatment of peripheral vascular disease and hypertension, surgical treatment of hypertrophic pyloric stenosis and ileostomy and colostomy have all been included in this edition. The surgical specialties units have been amplified with new material on corneal transplantation, retinal detachment and enucleation and fenestration.

The arrangement of subject matter is in units according to anatomic systems, although a change of sequence has been made to afford greater adaptability in teaching. Each unit is followed by a list of references and suggested reading, and more than 300 illustrations are included in the text. The type face and spacing have been changed to promote rapid reading. This book has considerable merit as a textbook for students and as a reference source for graduate nurses. It not only provides a thorough, up-to-date review of surgical nursing but also, through its approach, encourages a progressive attitude toward nurse-patient relations.

Nursing in Prevention and Control of Tuberculosis. By H. W. Hetherington, M.D., M.R.C.P., Chief of Clinic of the Henry Phipps Institute of the University of Pennsylvania, Philadelphia, and Fannie W. Eshleman, R.N., B.S., Supervisor of Public Health Nursing of the Henry Phipps Institute of the University of Pennsylvania, Philadelphia. Third edition. Cloth. $4.50. Pp. 361, with illustrations. G. P. Putnam's Sons, 2 W. 45th St., New York 19, 1950.

In this revised edition the authors attempt to present the subject of tuberculosis in all its aspects in such a manner that it will be readily understood by nurses without special training in the tuberculosis field and at the same time be sufficiently detailed to fill the needs of the more advanced student. Emphasis is on present day concepts of the tuberculosis patient and the health supervision of the patient's family.

Pertinent aspects of diagnosis, treatment, management and rehabilitation are thoroughly discussed. Furthermore, there are chapters dealing with the problems incident to tuberculosis in pregnancy, in infants and in children. Similarly, nursing care technics are presented which will provide effective practical approaches in the care of the patient in the hospital, the dispensary or clinic and in the home. Forcefully stressed are the implications of this disease to the community by the presentation of family case studies illustrating the insidious capacity of the disease for spreading throughout entire family groups. Interested in preventive measures to control this disease are various community agencies, whose functions and interrelated responsibilities with the nursing profession are pointed out.

In summary, this book typifies in its approach to the problems of tuberculosis the thinking which has been responsible for the present notable decline in the incidence of the disease. The value of improved care and public health methods of prevention are emphasized throughout. Inasmuch as this attitude is assuming ever-increasing significance in the present approach to diseases in general, it is particularly important that nurses in their formative stage of professional development be exposed to such a philosophy. For this reason, in addition to its clear comprehensive review of the subject of tuberculosis, this book has merit as a textbook for nurses.

Non-Gonococcal Urethritis Including the Genital Manifestations of Local and Systemic Diseases and Infestations of the Urinary Tract with Protozoa, Metazoa and Fungi. By A. H. Harkness, M.R.C.S., L.R.C.P., Joint Director of the Endell Street Clinic, St. Peter's and St. Paul's Hospitals (Institute of Urology), London. Cloth. $10. Pp. 424, with 167 illustrations. The Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1950.

This monograph is confined to a rather limited but important field of infection. The description of the various forms of nongonococcal urethritis, together with specific therapy indicated, is most thorough. The illustrations and plates are exceptionally well done and are instructive. It is evident that the author was well qualified to write on this subject and that he had unlimited material to draw from. However, one cannot help wondering whether the differentiation that is made among the various forms of urethritis may be of more academic interest than practical. The monograph should be of value as a reference book to those interested in urethritis. It is much too detailed to serve as a textbook for undergraduates.

Principles of Ophthalmology. By Thomson Henderson, M.D., Senior Surgeon, Nottingham and Midland Eye Infirmary, Nottingham. Cloth. $4.50. Pp. 230, with 63 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1950.

The title of this book is misleading. It is a series of essays by an original thinker whose conclusions often run counter to what is generally accepted as fact in ophthalmic physiology and pathology. There are chapters on the angle of the anterior chamber, the intraocular pressure and glaucoma, the mechanism of accommodation and several other ophthalmologic subjects. The author's conclusions are drawn largely from comparative anatomy of the eyes of mammals. The book is stimulating but not to be read without a critical attitude.

Cerebral Palsy. By John F. Pohl, M.D., Orthopedic Surgeon, Michael Dowling School for Crippled Children, Minneapolis. Cloth. $5. Pp. 224, with 131 illustrations. Bruce Publishing Company, 2642 University Ave., St. Paul 4, Minn., 1950.

Until the last 10 years the patient with cerebral palsy was indeed the forgotten child. As an outgrowth of the interest and work for crippled children in general, of the combined federal and state programs for the care of the physically handicapped child and the tremendously expanded work of the National Society for Crippled Children and Adults, a patient with cerebral palsy now seems to be well on the way to becoming a favored child. Facilities and programs for the care of children with cerebral palsy are being added each year. There is the United Cerebral Palsy Associations, an organization now engaged in raising funds for hospitals and schools which will be devoted exclusively to the care and education of crippled children of this special category.

Pohl attempts to explain the etiology and pathology of cerebral palsy. The simplest possible language is used to describe the different types of this disease. The plan of treatment described by Dr. Pohl is confined for the most part to education of the child through supervised activities in which he must learn how to help himself. The need for the child to learn relaxation along with neuromuscular training is discussed. The modalities which are used as part of the program, including physical therapy, occupational therapy and speech training are duly emphasized. Surgical procedures are not discussed in detail. While there is nothing that might be considered either new or revolutionary, the book is clearly written and easy to understand. It should be of value to those who wish to become teachers in the field of cerebral palsy and to parents of children who are crippled by this disease.

Medical Parasitology for Medical Students and Practicing Physicians. By William G. Sawitz, M.D., Associate Professor of Parasitology, Associate in Medicine, The Jefferson Medical College of Philadelphia. Cloth. $4.25. Pp. 296, with 90 illustrations. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St., Philadelphia 5, 1950.

Here is a useful manual for the guidance of both laboratory and clinical students of parasitology. It presents the subject from the medical viewpoint without omitting essential zoological information and concepts. Not designed or intended to replace textbooks on the subject, it is nevertheless complete from the standpoint of essentials for the training of parasitologists. The organization, definitions and classification of various subdivisions of the subject are unusually clear and to the point. The book includes essential illustrations, most of which are excellent, though occasionally they are too diagrammatic. More color could have been employed to illustrate characteristic staining reactions, as in the case of malarial parasites. The chapter on treatment is complete to the point of inclusion of various pesticides and repellents as well as modern agents for the therapy of insect bites and internal parasites. Not the least important features are the vocabulary of technical terms and a carefully prepared index.

We Pass This Way. By Charles A. Cooper. Cloth. $3.50. Pp. 183. Exposition Press, 251 Fourth Ave., New York 10, 1950.

This is a novel written by a physician who practices in a small town in northern Michigan. The action of the story takes place in a copper mining village in the section where the author lives. It demonstrates the fact that to be a good physician one must be a keen observer of human nature, and Dr. Cooper has shown in this story that he has this quality. He has reduced to the printed page the thoughts and actions of many characters from all walks of life. These people for the most part lead drab, circumscribed lives and only occasionally break through the drabness. The author states in the first chapter, "The land don't change much. Men pass this way, and leave their marks, but a few years, an' you can't hardly tell there was a thrivin' community here. Mighty near never left a trace." The story makes interesting reading.

QUERIES AND MINOR NOTES

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

VOCAL TRAINING

To the Editor:—Is it possible to increase the potency of a speaker's or a singer's voice? To obtain a long emission without being tired? To extend the gamut tonality in which range a voice may develop? To free a timbre from unpleasant harmonics? Which scientific methods are adequate to obtain these results? Is there any treatise dealing with these problems and with the hygiene and care of the voice for the use of speakers and singers? Is there any specialist in phonology in an established school for declamation, singing or similar arts whom it would be possible to consult in specific cases? M.D., Havana.

Answer.—It is possible to increase the potency of a speaker's or a singer's voice, obtain a long emission or speak continuously without fatigue and to free the timbre from unpleasant harmonics. The pitch range of a voice may be extended but may involve great harm to the vocal cords in most persons. Forcing the voice in any manner is harmful. Many vocal difficulties are brought about by irritation from misuse of the voice and often result directly from vocal instruction by vocal teachers who are not scientifically trained. Scientific methods have been developed in which ease of phonation, natural pitch range, diaphragmatic breath control and avoidance of glottal attacks are of the most importance. A recommended book dealing with some of these problems is "Training the Speaking Voice," by Virgil Anderson (New York, Oxford University Press, 1942). No adequate book has been published dealing with these problems, since it is a subject which only in recent years has been placed on a scientific basis.

Scientifically trained phonologists are few. They are persons with university degrees in speech therapy who have specialized in voice. Some of the certified members of the American Speech and Hearing Association (Speech Clinic, Wayne University, Detroit, Mich.) are qualified to do this work. The departments in the United States which have specialized in voice are the School of Speech, Northwestern University and Temple University Medical School. Work of this type should be conducted only in consultation with laryngologists.

LEAD AND ZINC INDUSTRIAL HYGIENE

To the Editor:—Please furnish me with data concerning (1) an easily performed, rapid test for lead in urine and for zinc, (2) a method of preparing the copper sulfate solutions for the falling drop method of determining specific gravity of blood, (3) toxicity of zinc, symptoms and treatment and (4) a short bibliography of material dealing with lead and zinc industrial hygiene. M.D., California.

Answer.—1. There is no "easily performed, rapid test for lead in urine." All of several available quantitative tests are exacting and require skill above the usual clinical laboratory level. The details of any one method are too extensive to permit presentation here, but full data may be obtained in the book by H. B. Elkins (The Chemistry of Industrial Toxicology, New York, Wiley and Sons, Inc., 1950) or that by M. B. Jacobs (Analytical Chemistry of Industrial Poisons, Hazards, and Solvents, New York, Interscience Publishers, 1949, vol. 1). The procedures required for zinc determinations similarly may be found in the publications mentioned.

2. The exact strength of the several solutions of copper sulfate as applied in the falling drop method of specific gravity of blood measurement is critical and calls for precise standardization. On this account it is somewhat impractical to prepare these test solutions in small laboratories. Prepared materials are supplied by Anachemia, Ltd., through any good laboratory supply firm. The required solutions and procedures are discussed in an article by Atchley and co-workers (Copper Sulfate Method for Measuring Specific Gravities of Whole Blood and Plasma, *J. Lab. & Clin. Med.* 30:830, 1945) and in one by Muirhead and co-workers (Practical Observations on the Copper Sulfate Method for Determining the Specific Gravities of Whole Blood and Serum, *Surg.-Gynec. & Obst.* 82:405, 1946).

3. By some definitions zinc is not a toxic agent, but some of its salts are, such as the chloride. Freshly produced zinc oxide in the form of fume is one of the several metals that may lead to metal fume fever, better known as zinc chills or zinc ague. This acute disease (there is no known chronic form) arises oftener in foundries where zinc is a constituent of the metal poured, such as brass foundries. Several hours after exposure, the victim undergoes pronounced chilling resembling a malarial chill and complains of pronounced and unquenchable thirst; there may be present an elevated temperature. All this may be followed in a few hours by pronounced fatigue, malaise and distaste for food. Ordinarily no time is lost from work. Day by day these episodes may recur in varying severity. Real treatment is elimination of exposure. Otherwise the treatment is symptomatic and treatment may not be required.

4. The following books furnish both pertinent data and extensive bibliographies: "Lead Poisoning," by A. Cantarow and M. Trumper (*Baltimore, Williams & Wilkins Company, 1944*) and "Industrial Hygiene and Toxicology," by F. A. Patty (New York, Interscience Publishers, 1949, vol. 2).

FEVER OF UNDETERMINED ORIGIN

To the Editor:—Many patients with "fever of undetermined origin" receive the usual laboratory examinations, get well and leave the hospital without a diagnosis. I feel that more exhaustive studies can be done in these patients. Please discuss the differential diagnosis in the following hypothetical case and name the laboratories where the more unusual types of studies can be done: A 30 year old, previously healthy white man enters the hospital because of malaise and fever. His temperature over a 14 day period is normal. Repeated roentgenograms of the chest, urinalysis and blood cultures are not revealing. Stool cultures are negative. Results of serologic studies and blood agglutinations for brucellosis, Salmonella, typhoid, paratyphoid, tularemia and heterophil antibodies are negative. The blood cell count is normal.

Richard R. Grayson, M.D., Lubbock, Texas.

Answer.—In the foregoing case, of an acute febrile illness occurring in a previously healthy man with quick return of the temperature to normal, one can rule out certain well known causes of "fever of undetermined origin," including carcinoma, lymphoblastoma, leukemia and probably bacterial infections such as tuberculosis. The commonest cause of this type of illness is a virus. To define the virus responsible for the illness is difficult. There are a number of viruses causing respiratory disease which may cause an atypical clinical picture as described. The diagnosis of viral diseases is time consuming and can be carried out only by special laboratories. The laboratories of many state boards of health, as well as the Communicable Disease Center of the United States Public Health at Atlanta, Ga., are prepared to carry out these studies. In general, two methods are utilized for identifying the viral disease. One is by isolation of the virus from the tissues, body fluids or secretions by appropriate procedures. The other method is by ascertainment of the presence of antibodies in the blood. For the latter purpose, the serum would be collected under sterile conditions during acute and convalescent stages of the illness. Further discussion of this subject is included in "Routine Laboratory Diagnosis of Virus and Rickettsial Diseases," by Albert Milzer (*J. A. M. A.* **143**: 219 [May 20] 1950.)

ABSCESSED TEETH

To the Editor:—In acute dental alveolar abscess with swollen jaw and fever, what is the medical management prior to extraction of the abscessed tooth? What measures are recommended after extraction of a tooth which results in similar symptoms? From time to time the general practitioner is asked to treat this condition.

Irving I. Crouse, M.D., Buffalo.

Answer.—Treatment of acute infections about the jaws does not differ basically from treatment of similar infections elsewhere. The major consideration is the proximity of the infected tooth to the bone and the concomitant bacteremia. The patient should be adequately prepared with antibiotic therapy prior to the extraction. Roentgenographic examination and a complete blood cell count are also desirable. Postoperative treatment should include the use of a saline mouth wash or irrigation. Extraoral heat and surgical drainage and hospitalization should be considered. Antibiotic therapy, diet, fluid intake and analgesics are important aspects of medical management. Further information may be obtained in standard oral surgery textbooks.

INFANTILE GENITALIA

To the Editor:—A 10 year old boy has a penis less than 2 cm. in length; the scrotum is small, and the testes are peanut size. The organs have not shown any development from infancy. He is sensitive about it, as the boys at school tease him. He is a little over normal height and weight, and in the past few months he has become a bit chubby. There may be a slight tendency toward girdle obesity. He was delivered by cesarean section and has always been of "frail" health. He seems bright in his school work. Would hormone therapy be indicated? Is testosterone or pituitary gonadotropic hormone recommended and in what dosage?

Owen Wheeler, M.D., Portland, Ore.

This inquiry was referred to two authorities, whose respective replies follow.—Ed.

Answer.—One frequently sees boys, prior to adolescence, in whom the genital organs may be described as infantile. It is remarkable how often this defect is remedied by adolescence. It would be unwise to try hormone therapy at this time, because when it has been employed prior to adolescence the results have been anything but satisfactory; in some cases such treatment has been injurious. It would be well to wait until after adolescence and employ these therapeutic agents only in case the genital organs remain abnormal. The patient should be informed of this fact and told not to despair of eventual normal manhood.

Answer.—This boy is nearing the age at which normal pubertal development usually occurs. One probably would be wise to wait until he is 12 or 13 before considering hormone therapy. The fact that the testes are in the scrotum suggests that, if he does not develop sexually, the diagnosis would be secondary hypogonadism. This means that there is insufficient stimulation of the gonads by the pituitary. However, the gonads may prove to be refractory to pituitary stimulation. One should try chorionic gonadotropins in this case first. This substance is mostly luteinizing hormone, producing its effect on the interstitial cells of the testis, causing the testis to produce androgen. Suggested dosage is 500 units of chorionic gonadotropin twice a week for two or three months. If no effect is observed, then androgens should be given in small doses to permit determination of a maintenance dose, such as 10 mg. of methyl testosterone orally once a day for a month or six weeks, the dosage being varied depending on response. This is substitution therapy and would hardly be expected to produce a normal set of gonads; it would merely fill the body needs for androgens.

PARKINSONISM

To the Editor:—Please discuss treatment of idiopathic parkinsonism in the light of Sigwald's report of benefit from 10-(2-diethylaminopropyl) phenothiazine hydrochloride (RP 3356), abstracted in *The Journal* March 18, 1950 (page 853). P. W. Van Metre, M.D., Rockwell City, Iowa.

Answer.—Both RP 2987 (diparcol) and RP 3356 (parsidol) have been reported on in the French literature by Sigwald. An elaborate technic for their clinical use was worked out by him, the dose being arranged throughout the day so that the side effects were minimal. When they did appear, Sigwald counteracted them with specific drugs, such as *d*-amphetamine sulfate for drowsiness. In these circumstances, the results were impressive. Other workers are less enthusiastic, and in one series only one third of the patients receiving diparcol showed improvement and only one half receiving parsidol were benefited. It is possible that the discrepancies between these reports are due to the fact that the American investigators did not carry out in detail the technic suggested by Sigwald. Both drugs are still under investigation and are not acceptable at the present time as drugs that should be widely used for parkinsonism.

OIL FORCED INTO FINGER

To the Editor:—A man punctured his finger with a drill. The drill is hollow, and a stream of oil constantly flows through it under pressure. The finger was immediately tense and swollen, and the man had great pain. It was incised in the flexor surface to the tendons and allowed to remain open. The finger gradually healed, but it has remained nearly double its normal size and is tense and indurated. This swelling extends down into the hand along the second metacarpal. It is now almost five months since the accident, and the condition seems to be more or less stationary. There is practically no useful function in this finger. The man heard that injections of ether have been used for conditions similar to his. Has such treatment been successfully used? W. H. Cole, M.D., Elizabeth, N. J.

Answer.—Oil forced into the soft tissues causes severe and extensive fibrous tissue reaction. Since five months have elapsed since the accident and there is no useful function of the finger, the only practical solution of the problem is amputation. If this is carried out, every effort should be made to excise the scar tissue about the metacarpal as completely as possible. Injections of ether would add further insult to the injury which has already been sustained.

THE SWIMMING HOLE AND POLIOMYELITIS

To the Editor:—The local health board has posted a small stream against swimming for the past two years, believing it to be a possible source of poliomyelitis for the following reasons: Once weekly the town garbage is dumped and burned with gasoline in an area 150 yards from the stream; about 1,000 yards downstream a small dam forms a popular swimming hole. The posting of this latter spot has aroused a certain amount of community ire. Are we justified in supposing that poliomyelitis can be a menace here? N. E. Patrick, M.D., Factoryville, Pa.

Answer.—It does not seem likely that the garbage dump to which you have referred is a potential source of poliomyelitis virus, especially since it is regularly disposed of by burning. In addition to this, the virus of poliomyelitis has never been recovered from swimming pools; in the one or two recorded instances where it has been isolated from moving streams the opportunities for contamination were much more obvious than they appear to be in this instance. It may be that the local health officer has found the stream to be otherwise polluted, and, therefore, closure of the swimming hole might be justified but not primarily because of the danger of poliomyelitis.

PYORRHEA AND RETINAL HEMORRHAGES

To the Editor:—A 27 year old woman decided some months ago to have her teeth removed because of pyorrhea. She has been a diabetic since the age of 11 years. She was being treated by another physician and was under good control for diabetes; she was on a balanced diabetic diet and took 60 units of protamine zinc insulin a day. The dentist then extracted all her lower teeth; a short time after this she had massive hemorrhages of the right eye. No relation between the extractions and hemorrhage being evident, extraction of the upper teeth was then begun, with removal of four or five at a time. Retinal hemorrhages then began to develop in the left eye. Is there any relation between the removal of such teeth and retinal hemorrhages in diabetics? Once retinal hemorrhages occur in these patients is there any cure for them? What is the prognosis?

Abraham A. Kaufman, M.D., Binghampton, N. Y.

Answer.—This interesting problem cannot be answered with certainty. It is also unusual. There is nothing which would relate the massive retinal hemorrhages to the extraction of teeth. They could be coincidental. They could be related to the surgical procedures if a general anesthetic was used, though anesthesia is not mentioned in this case. The safest procedure to be used for extractions should consist of a constantly good control of the diabetes and the removal of a small number of teeth with local nerve block.

Therapy for the retinal hemorrhages should also consist of good management of the diabetes. Hemorrhages are concomitants of the disease and may be expected. There is always some improvement of the acute phase, with absorption of the blood in the retina, but a scar and impairment of vision often results. Attempts to treat the hemorrhage with vitamin P (rutin) have not had constant success. The hemorrhagic condition is not related to the vitamin C intake. The prognosis is not entirely serious, since the appearance is not always progressive and may subside. If retinitis proliferans accompanies the event, the prognosis is poor.

SUBACUTE COMBINED DEGENERATION OF SPINAL CORD

To the Editor:—My condition has been diagnosed as lateral posterior sclerosis of the spinal cord. What is the cause, prognosis and accepted treatment for this condition? Please give the differential diagnosis between lateral posterior sclerosis and multiple sclerosis. M.D., Missouri.

Answer.—Posterolateral sclerosis of the spinal cord is perhaps better termed and is usually referred to as subacute combined degeneration of the spinal cord. The disease syndrome has manifestations of lesions in the spinal cord and peripheral nerves. It is usually associated with pernicious anemia but infrequently is also seen in secondary anemia and severe dietary inadequacies. The etiology has not yet been adequately described. Some authors have held that subacute combined degeneration was the result of neuroanemia. Offered in support of this contention was the fact that in most cases the thoracic portion of the spinal canal, which has a relatively poor blood supply, was the region most seriously involved. It is more likely that the disease results from effects of nutritional deficiencies. It has been described as occurring in pellagra, sprue, carcinoma of the stomach and hepatic disease. If recognized early in the course and before spinal cord changes are severe, neurological manifestations are frequently reversible. Treatment must be directed at the underlying or associated disease. In the treatment of pernicious anemia, the administration of potent liver extracts and/or vitamin B_{12} will protect against the development or effect remission of subacute combined degeneration of the spinal cord. Pteroylglutamic acid is not effective in this regard. The provision of vitamin B complex as a part of the therapeutic regimen may control symptoms of peripheral neuritis, which frequently accompanies this disease.

Subacute combined degeneration of the spinal cord is characterized by sensations of numbness and tingling of the hands and feet and by increasing paralysis of the legs and hands. These symptoms may also be associated with multiple sclerosis, which may have a wide variety of neurological manifestations and may simulate many other diseases of the central nervous system. Multiple sclerosis chiefly affects persons in the age group of 20 to 35 years, whereas subacute combined degeneration of the cord occurs more commonly after middle life. The latter disease is progressive, presents no ocular symptoms and produces loss of sphincter control late in its course. Deep reflexes are usually absent. In contrast, multiple sclerosis is remittent in its course, is associated with transient diplopia, blindness and blurring of vision and affects sphincters in its early stages. Deep reflexes are rarely absent in this disease. The demonstration of macrocytic anemia and gastric achlorhydria is evidence in favor of the diagnosis of subacute combined degeneration of the cord, since this is so commonly associated with pernicious anemia.

ALCOHOL FOR ANGINA PECTORIS

To the Editor:—I have a moderate degree of coronary sclerosis and a slight disturbance of the peripheral circulation. I have been advised by competent physicians to use a moderate amount of whiskey. I have been using six year old whiskies, bonded or straight bourbon. However, I have been advised that blended whiskey, made of whiskey and neutral spirits, is just as good for me. Is this correct? M.D., Ohio.

Answer.—Alcohol in moderate amounts has been used for the relief of angina pectoris ever since it was first recommended by Heberden. Alcohol is of no value in the management of the acute attack, inasmuch as the attack usually subsides spontaneously, before alcohol could have an effect. For this reason the nitrites are of more value in aborting the acute attack. Many physicians suggest that alcohol be used in coronary artery disease, because of its vasodilating effects and because of its analgesic and sedative actions. These effects are due to the alcohol itself and not to the extractives or aromatics. Aging of alcohol acts to change the fusel oils and aromatic compounds, resulting in the removal of irritants which are present in some of the neutral spirits, and provides special aromas, depending on the method of aging. These latter are of gustatory value only. Blended whiskies are just as efficacious in producing the desired effects in angina pectoris as are the bonded varieties. A word of caution should be sounded against the danger of habituation.

HEMIHYPERTROPHY

To the Editor:—A girl born Sept. 12, 1946, after an uneventful delivery, weighed 9 pounds 7 ounces (4,281 Gm.) at birth. At 2 weeks of age she seemed to have choking spells with slight cyanosis, followed by a minute or two of limpness. There were no convulsions. The child had two spells, and in one the lips were decidedly cyanosed and the face very pale. No irregularity of the heart was noted. The temperature, urine and bowel movements were normal. The thymus appeared decidedly enlarged on fluoroscopic examination. In the third week of life the mother noticed that the left cheek, the left arm, the left side of the body and the entire left lower extremity were larger than the right. Roentgenograms of the long bones on both sides showed no difference in size between the two. A pediatrician diagnosed hemihypertrophy due to an ovulation-fertility phenomenon, in that the pregnancy should have been a twin pregnancy, so that the end-product shows a twin effect. What will this girl look like as an adult? Would plastic surgery result in a closer to normal appearance? Could some abnormality of the great vessels or the heart produce this picture? M.D., Minnesota.

Answer.—Hemihypertrophy is a rare congenital abnormality, the cause of which is unknown. In not a few instances it has been associated with retardation in mental development.

It is not possible to predict the future appearance of a given child who exhibits the condition. However, it is stated that the hemihypertrophy may partially or entirely disappear, at least so far as it would be noticeable to other persons. There is no indication for the employment of any plastic operation, especially since improvement can be expected with advancing age.

TINNITUS AURIUM

To the Editor:—For best results in tinnitus aurium, how frequently may vitamin A (ampuls of 1 cc., 50,000 units) be injected?

M.D., Pennsylvania.

Answer.—The generally accepted treatment with vitamin A for tinnitus consists of giving 1 cc. (50,000 units) intramuscularly twice a week. A six week period of treatment is usually sufficient to indicate effectiveness. There is, however, no well controlled clinical study to indicate the effectiveness of vitamin A in the treatment of tinnitus.

ANTIBIOTICS BY MOUTH AND VITAMIN ABSORPTION

To the Editor:—A well informed physiologist made the statement that all patients subjected to oral treatment with chloramphenicol, aureomycin or terramycin should receive concomitant parenteral or intravenous supportive vitamin therapy (particularly B complex and C), because these antibiotics drastically retard or wholly inhibit absorption of vitamins from food or from orally administered vitamin concentrates. Is this true?

M.D., Texas.

To the Editor:—Reactions to oral administration of aureomycin have been occurring with disturbing frequency in our locality. They consist of stomatitis with fissuring of the angles of the mouth and, frequent, vaginitis and inflammation of the rectum, similar to reactions seen in some patients given penicillin orally. The patient complains of a burning sensation from mouth to anus and sometimes diarrhea. I would appreciate any recommendations you can offer.

Donald E. Minch, M.D., Lakeview, Ohio.

Answer.—Satisfactory evidence is lacking that any of the newer antibiotics either retard or inhibit the absorption of vitamins from ingested foods or from capsules and tablets of such vitamins administered by the oral route. Disturbances in the function of the colon do occur when aureomycin, chloramphenicol or terramycin are given in appreciable doses. For example, bilirubin appears in the stool. This occurs because these antibiotics suppress the growth of or actually kill susceptible, normally occurring bacteria in the colon and in other places, such as the mouth and pharynx. When this occurs, organisms which are resistant to the bacteriostatic or bactericidal effects of these antibiotics replace the normal bacterial flora. Naturally, the suppression of normally occurring bacteria, especially in the colon, brings about pronounced changes in bacterial metabolism. This accounts for the disturbances so frequently noted in the stools and the elimination habits of patients who are receiving these newer antibiotics. When aureomycin, chloramphenicol or terramycin are being administered, lesions may occur on one or more of the mucous surfaces of the body. It has been established that in certain patients these lesions are produced by, or become infected with, yeastlike organisms, of which Monilia are the commonest. Also, it seems that lesions of the mucous membranes may sometimes be due to vitamin B complex deficiencies when the newer antibiotics are being administered. Therefore, when mucous membrane lesions make their appearance, one should first establish whether these lesions are due to an infection with Monilia or to a vitamin deficiency. When this determination has been made, proper therapy may be instituted.

Evidence seems to be accumulating that it is logical to administer by mouth the recommended requirements of vitamins (especially those of the B complex) as a supplement to dietary vitamins, to all patients who are receiving 2 Gm. or more of aureomycin, chloramphenicol or terramycin per day, for a period of five or more days. Patients receiving these doses of these antibiotics frequently do not have a normal vitamin intake from food because they are nauseated. There is little if any evidence that vitamins should be administered parenterally or intravenously to patients receiving these antibiotics, unless they are very ill or unless the physician feels that the patient's vitamin intake had been deficient prior to treatment with any of these newer antibiotics.

COMBINED INJECTIONS

To the Editor:—Can tetanus toxoid and 400,000 units of aqueous penicillin (procaine penicillin G and penicillin G, crystalline potassium) be administered together in a syringe through the same needle puncture without any harm to the action of each? Can tetanus antitoxin, following the skin test, be combined with 400,000 units of penicillin for injection? Frederick H. Bowen, M.D., Jacksonville, Fla.

Answer.—The combination of penicillin with either tetanus toxoid or tetanus antitoxin should cause no harm to the action of any of the ingredients. However, if the contents remain long in the syringe before expulsion, there may be blocking of the needle.

LOW SODIUM DIET

To the Editor:—A patient has raised the question as to whether a mold inhibitor, sodium propionate, sold under the trade name of mycoban, would be sufficient to affect a low sodium diet. M.D., Missouri.

Answer.—It is necessary that one be on guard against concealed sources of sodium in the diet. An example, which is often unsuspected, is the custom of many restaurants of adding salt to their coffee. Inquiry of several large baking companies elicits the information that most of them do not use mold inhibitors. Calcium propionate is used in some baked articles. Sodium propionate, when employed, is in the proportion of 2 to 4 ounces to 100 pounds of flour, or about 160 pounds of bread. The amount, therefore, is too small to be significant in a low sodium diet for ordinary practical purposes. It can be significant only under experimental or exceptionally severe conditions.

STERILIZATION OF LANCETS

To the Editor:—Since publication of the article by Dr. Walter Ward and me in THE JOURNAL (June 17, 1950) I have received inquiries concerning the proper sterilization of a lancet used for finger or ear puncture when doing blood cell counts, so as to avoid the possibility of transmitting a virus infection. Many physicians do not have autoclaves or ovens in their offices, and the question of a substitute arises. Some suggest having enough blades on hand so they can be put in a sterilizing solution overnight. Would this be better than using boiling water for 20 to 30 minutes?

Clifford Kuh, M.D., Oakland, Calif.

ANSWER.—Chemical agents cannot be relied on to destroy the virus of homologous serum jaundice. In view of the availability of electric hot plates, pressure cookers and miniature, electrically operated autoclaves, there is no excuse for one's not exercising adequate procedures for the disinfection of instruments by heat. Some clinical laboratories are guilty of careless handling of syringes, needles and lancets utilized for the collection of blood specimens.

Contaminated instruments may be placed in solutions of chemical disinfectants prior to heat treatment. A preliminary heat treatment in boiling water for 15 minutes will minimize the danger of accidental infection. Organic material such as blood and pus will coagulate during the preliminary heating; the larger particles can be removed by mechanical cleansing, and the smaller particles will dissolve in hydrogen peroxide or dilute ammonia water. Final disinfection by heat can be effected by submersion in boiling water for at least 15 minutes, the timed interval to begin after the water begins to boil.

Lancets utilized for collection of micro blood specimens from the finger or ear lobe should be solid and without holes or sleeves. A clean, sterile instrument should be utilized for each subject. Lancets may be subjected to the procedure outlined above, or terminal sterilization may be effected in the flame of a Bunsen burner or alcohol lamp.

Syringe technic in preventing serum jaundice is described in Queries and Minor Notes, page 579, June 11, 1949.

TINY VENULES ON THIGHS

To the Editor:—Several white women, aged 20 to 30, have large numbers of superficial telangiectases on their thighs. Please discuss etiology and treatment.

Richard R. Grayson, M.D., Lubbock, Texas.

ANSWER.—Often such vessels are composed of tiny venules rather than telangiectases. They are of no importance other than that they constitute a cosmetic defect. They may be destroyed by electrolysis, by punctate electrocautery or by careful injection of a drop of a sclerosing agent, but the results obtained are in many instances not satisfactory.

POSTURAL HYPOTENSION

To the Editor:—A patient apparently has postural hypotension. She is 65 years old and until six months ago had had essential hypertension (with a systolic pressure said to be around 220) for years. Six months ago she had a coronary occlusion, for which she was hospitalized for two weeks and in bed at home for two weeks. About two weeks later she had an illness, diagnosed as a virus infection. Then she complained of weakness and dizziness on walking; she has remained in bed since, getting out only to go to the toilet or for occasional meals. The patient is described as somewhat given to complaining, always busy but of very limited interests. Her husband has been dead for 10 years. About a year ago, a niece was killed in an automobile accident. This patient complains of burning and pains in the palms and soles, fulness after eating and lack of appetite. She has attacks of anxiety and once vomited. Another time she complained of the room turning about her if she closed her eyes. Reassurance seemed to relieve these episodes. The only positive observations after a week of hospitalization were a duodenal diverticulum (second portion) and postural hypotension. At rest, her blood pressure is usually 170/100. On standing or walking for a minute it drops to 120-130/80-90. These observations were repeated many times. Ephedrine sulfate, amphetamine sulfate, a visammin preparation by mouth and desoxycorticosterone had no apparent effect on the postural hypotension. A neurologist could find no organic lesion and felt that many of the patient's symptoms could be explained on a psychoneurotic basis; nevertheless, he was unwilling to let that be the entire diagnosis and suggested the patient be watched for further development.

M.D., New York.

ANSWER.—One can only guess the cause of the hypotension in this patient, the most likely guess being lack of tonic response of the visceral blood vessels due to the antecedent virus infection. Possibly the myocardium has been sufficiently weakened as the result of infarction so that it does not respond adequately. This seems unlikely. Some disturbance of the sympathetic nervous system is still another possibility, which one could test by blocking the ganglions with tetraethylammonium chloride to determine whether blockage gives a less than normal vascular response when the patient assumes the erect posture. Since the mechanism is unknown, one can only recommend empirical measures: The patient should (1) sleep in a bed raised at the head, (2) have a corset designed to assure greater return of blood from the abdominal area to the heart, (3) exercise to strengthen the muscles of the abdominal wall, (4) take moderate outdoor exercise and (5) discontinue taking drugs.

OSTEITIS DEFORMANS

To the Editor:—Please give the course of treatment for Paget's disease (osteitis deformans) in a 53 year old man? Is testosterone of any value?

William Kershaw, M.D., Queens Village, L. I., N. Y.

ANSWER.—The etiology of Paget's disease is unknown, and there is no known effective treatment. If, as in some cases, there is pain associated with the condition, roentgen therapy may be of palliative value. Salicylates may help in the same manner. There is no proof that testosterone is of value. There are no published reports of adequately controlled series of patients treated with this hormone.

NOCTURNAL CRAMPS AND VOMITING OF PREGNANCY

To the Editor:—In the answer to the question on "Nocturnal Cramps and Vomiting of Pregnancy" in the July 8 issue, I wish to bring the following observations to your attention: The incidence of nocturnal leg cramps among our obstetric patients has been severe enough to warrant careful study as to the etiology. Our observations do not substantiate low calcium intake as being of etiological importance. Our patients are routinely maintained on supplemental calcium gluconate; yet 10 per cent complain of nocturnal leg cramps. Eliminating those patients with obvious varicose veins, we have been unable to establish any definite cause for this bothersome complaint. Our patients have experienced satisfactory and rapid relief from nightly administration of 50 mg. of diphenhydramine (benadryl®) hydrochloride. With this regimen, all symptoms usually vanish within five days. Recurrences are treated with spasmodic doses of diphenhydramine hydrochloride as indicated.

William G. Caldwell, Toluca Lake, Burbank, Calif.

To the Editor:—Several times in the past few years I have noticed questions regarding nocturnal leg cramps in Queries and Minor Notes. I have not seen, however, mention made of the most effective treatment for this condition, which consists of 5 grains (0.30 Gm.) of quinine sulfate at bedtime. This dose should be continued for five to seven days, after which in a majority of cases the condition will be relieved. Should it recur later, the medication should be repeated. The mechanism by which quinine helps probably has to do with its effect on muscle irritability. The cramps themselves are most likely to occur after excessive exercise, excessive perspiration with ingestion of large quantities of water or severe vomiting or diarrhea. They apparently are closely allied with chloride metabolism. I cannot give you the original source of this use of quinine. It was put in the literature several years ago by Dr. Foster Kennedy of New York. It had been noted as a by-product during the course of an inquiry into the treatment of spastic paralysis.

Robert J. Needles, M.D., St. Petersburg, Fla.

The above comments were referred to the consultant who answered the original inquiry. His additional comment follows. —ED.

I did not attempt to go into all the causes of leg cramps in my reply. I made no suggestion that it was due to low calcium intake but merely local calcium deficiency, that is, in the muscle. Another point is that, in spite of a deficient intake of calcium, the blood calcium levels usually remain normal. I have not used diphenhydramine hydrochloride in this condition, but I repeat that adding 30 drops of oleum percomorphum (natural) daily will almost without exception stop the leg cramps in about three to five days. If one reviews muscle physiology, it appears that these cramps are in some way related to carbon dioxide, lactic acid and local calcium metabolism. Track men frequently experience these cramps when overextending themselves.

ANXIETY OR CHOREA

To the Editor:—With reference to the query entitled "Anxiety or Chorea" in *The Journal* of August 12 (page 1380), I should like to call attention to the work done by my associates and me, which suggests that a large percentage of the cases of Sydenham's chorea are not related to rheumatic fever (Kagan, B. M., and Mirman, B.: Sydenham's Chorea: A Syndrome for Differential Diagnosis, *J. Pediat.* 31:322 [Sept.] 1947. Kagan, B. M.; Rosner, D., and Rosenblum, P.: Chorea [Sydenham's]: A Study of 58 Additional Cases, *Am. J. Dis. Child.* 78:306 [Sept.] 1949).

The fact that physical, roentgen and laboratory examinations disclosed no abnormalities except for evidences of incoordination, nervousness, grimacing and twitching does not exclude a diagnosis of Sydenham's chorea. If this was the first episode of chorea in this child and if the results of all the examinations are negative as reported and the erythrocyte sedimentation rate was determined within the first three weeks of the onset of the initial episode, it would appear most unlikely that this child has rheumatic fever. However, there is nothing at this time to help rule out a diagnosis of Sydenham's chorea. The association of a state of anxiety with Sydenham's chorea and the absence of any evidence of rheumatic fever, either during the episode or subsequently, are common.

EVALUATION OF SYMPATHECTOMY IN ARTERIOSCLEROTIC PERIPHERAL VASCULAR DISEASE

Chairman's Address

MICHAEL E DeBAKEY, M D
OSCAR CREECH, M D
Houston, Texas
and
JEROME P WOODHALL M D
New Orleans

In terms of incidence and morbidity arteriosclerosis constitutes the most important form of peripheral vascular disease and consequently deserves the most serious consideration However, until relatively recently the prevailing attitude characterizing the therapeutic approach to this problem was almost fatalistic Among the more important factors which have contributed to this point of view are the concept that arteriosclerosis is an inevitable consequence of aging and therefore an irreversible process, and the general belief that sympathectomy was indicated only in peripheral vascular disturbances characterized by vasospastic phenomena with little or no organic component With the encouraging results which followed the cautious extension of this procedure in selected cases of this disease greater interest was aroused in the potential benefits of this form of therapy During the past decade numerous reports have appeared attesting to the value of this procedure in obliterative vascular sclerosis and reflecting a more hopeful outlook in therapy [1]

ANALYSIS OF DATA

This report is concerned with an evaluation of our experience with this problem based on an analysis of 146 consecutive cases of arteriosclerotic peripheral vascular disease of the lower extremities treated by lumbar sympathectomy at the Charity Hospital in New Orleans The procedure was performed bilaterally in 55 cases, so that in the entire series there was a total of 201 sympathectomies The operation was generally performed through an anterolateral, extraperitoneal, muscle-splitting approach as previously described,[2] with removal of all the lumbar sympathetic ganglions and chain overlying the second to the fourth lumbar vertebrae Prior to sympathectomy all patients had been treated by the usual conservative measures with little or no success All patients were followed six months or longer; 75 per cent were followed more than one year, and 38 per cent from two to four or more years Although oscillometric plethysmographic and thermometric studies were done in a number of cases, in most instances the generally accepted clinical criteria were employed in the diagnosis and classification of the cases Because the presence of diabetes has been generally considered to contribute further to the seriousness of the problem and the difficulties of management, the patients were divided accordingly into diabetic and nondiabetic groups for purposes of comparison

Age—The age distribution was about the same for the diabetic and nondiabetic groups of patients (fig 1) Almost 90 per cent of the patients fell into the sixth, seventh and eighth decades The youngest and oldest patients were 40 and 82 years of age, respectively, and the average age was 60 years

Sex—Arteriosclerosis uncomplicated by diabetes is predominantly a disease of males, but in the presence of diabetes this difference in sex incidence is much less pronounced Thus, in our series the ratio of males to females among the nondiabetic patients was about 5 to 1, whereas among those with diabetes it was almost 1 to 2 (fig 2) This variation in sex incidence of diabetic and nondiabetic patients is probably a reflection of the general observation that diabetes is more frequently encountered in females and arteriosclerosis occurs far oftener in diabetic than in nondiabetic patients [3]

Race.—No significant racial factor was observed in our series, as far as the white and Negro races are concerned, since their incidence approximated those of the population for the two races in the hospital (fig. 3).

Duration of Symptoms.—Analysis of the duration of symptoms revealed several interesting observations, some of which were unexpected. For one thing, among both the diabetic and nondiabetic groups symptoms existed for a significantly longer period of time among the unamputated than among the amputated patients (fig. 4). For another, the duration of symptoms was much shorter for the diabetic than for the nondiabetic groups. The former observation was somewhat unexpected. Arteriosclerosis is generally considered a chronic, progressive, degenerative process which, as a consequence of occlusion of the arterial lumens, leads ultimately to ischemic necrosis of the part supplied by these vessels. It might be reasonably expected, then, that patients requiring amputation would represent the end result of long-standing disease, but in our series, at least, this has not been true. Eighty-five per cent of the patients requiring ablation had frank gangrene when first seen; yet the duration of symptoms was shortest in this group. This would suggest that there exists a more rapidly progressive form of the disease which is highly resistant to therapy.

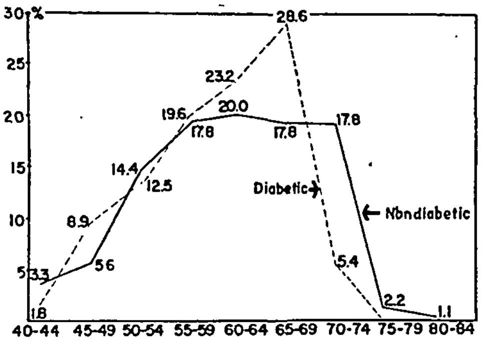

Fig. 1.—Age distribution of diabetic and nondiabetic patients. The average age for the diabetic was 60.0 and for the nondiabetic 61.5 years.

There is a striking difference in the duration of symptoms between the diabetic and nondiabetic groups of patients. The shorter period for the former group may be accounted for by several factors. The presence of diabetes would seem to hasten, and in a sense to telescope, the development of manifestations of arterial insufficiency and thus to cause the patient to seek medical attention earlier than he might otherwise. Perhaps the propensity of the diabetic patient for cutaneous infections is also a significant factor in this connection. Furthermore, there is a tendency for the diabetic patient to be more closely supervised, so that the likelihood of his receiving medical attention at the first sign of vascular impairment or infection is greater.

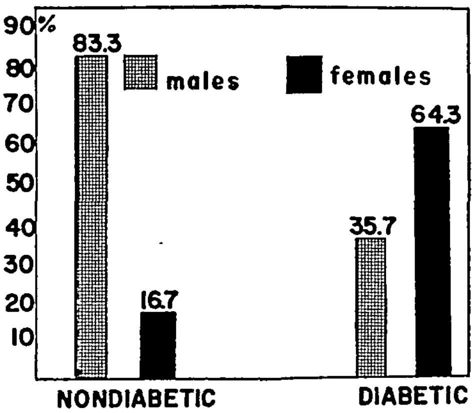

Fig. 2.—Incidence of lumbar sympathectomy by sex of patients.

Results of Therapy.—For purposes of simplicity and convenience of analysis the cases were divided into three categories, (1) no gangrene, (2) impending gangrene and (3) frank gangrene. The first group consisted of patients whose arterial deficiency was manifested by pain, either in the form of intermittent claudication or ischemic neuritis, but without evidence of alterations in the skin. Although the majority of these patients had pronounced restriction in walking distance and absence of peripheral pulses, they represent the least severe form of the disease and correspond closely to grade 1 of the classification proposed by de Takats and associates.[1b] The second group, impending gangrene, was comprised of patients who had, in addition to the manifestations previously noted, definite cutaneous changes including particularly pronounced discoloration, atrophy, glossy edema and other evidences of capillary stasis and severe arterial deficiency. The criteria for determining the selection of patients for the category of frank gangrene were obvious except for those with diabetes. In this group every effort was made to distinguish a primarily infectious from a gangrenous process.

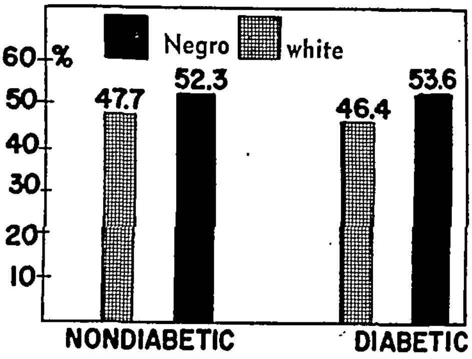

Fig. 3.—Incidence of lumbar sympathectomy by race of patients.

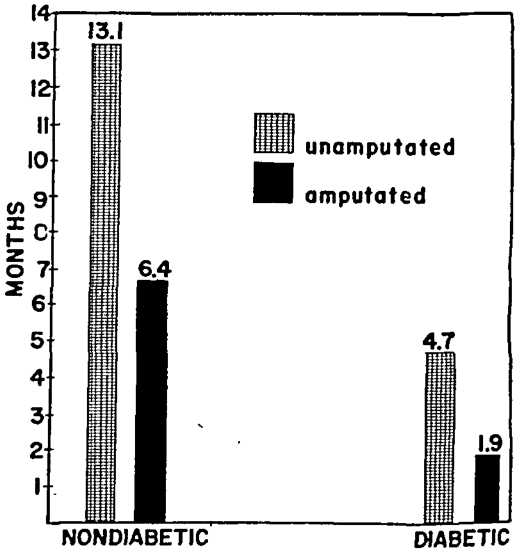

Fig. 4.—Average duration of symptoms in patients undergoing lumbar sympathectomy.

Again for the sake of simplicity and ease of analysis, results of therapy were classified into three categories, (1) improved, (2) unimproved and (3) amputated. Although in some instances certain special studies, such as oscillometric, thermometric and plethysmographic observations, were employed in assessing the results, in the majority of cases this was done on the basis of definite clinical evidence including relief of symptoms, increased walking distance, ability to return to work, improvement in color, texture and temperature of the skin, and salvage of an extremity in which impending or frankly gangrenous changes were present prior to operation. By amputated is meant a major amputation, i. e., above the ankle. If there was any doubt about the result, the case was classified as unimproved. For example, in a few instances even of frank gangrene in which amputation was not required after the sympathectomy the result was classified as unimproved because, despite salvage of the extremity, there persisted other severe manifestations that were more or less incapacitating. Furthermore, in order to provide a more critical evaluation of therapy, the results were assessed at the end of the follow-up period rather than immediately after discharge of the patient from the hospital following sympathectomy. In some instances apparent improvement occurred for a varying period of time after operation but ultimately, for example, at the end of six months or a year, the patient returned with ischemic necrosis necessitating amputation. Such a case was classified as amputated. It is, of course, recognized that by the rigid adherence to these criteria in assessing the results of therapy certain benefits of treatment, such as temporary salvage or prolongation of a viable extremity, better control of an infectious process and the ability to provide a low rather than a high amputation, are excluded from the final results of therapy. However, experience has emphasized the need for a rigidly objective and critical attitude in the assessment of results of treatment in peripheral vascular disease if accurate evaluation is to be achieved.

The best results were, of course, obtained in patients with the least severe disease, i. e., those in the "no gangrene" category in both the nondiabetic and diabetic groups (table 1). Even among the patients with impending gangrene a gratifying incidence of improvement was achieved in more than three fourths of the cases. It may also be observed that among the patients with frank gangrene it was possible to secure a viable, useful extremity in almost a fourth of the group without diabetes and in almost half of those with diabetes. The strikingly better results obtained among the diabetic patients in this category suggest that the distinction between a truly infectious and an actually gangrenous process may not always have been accurately made. These results also suggest that the severity of ischemic manifestations in the diabetic patient may not accurately reflect the degree of the occlusive process in the vascular bed. The presence of diabetes may tend simply to accentuate the manifestations of ischemia. In other words, although the patient with diabetes may have clinical manifestations equally severe and comparable to those of another without diabetes, the underlying occlusive vascular process may be less severe in the former than in the latter. This hypothesis gains some support from the previously observed differences in the duration of symptoms for the two groups of patients. In any case the diabetic patient certainly has an equally good chance of obtaining benefit from this form of treatment as the nondiabetic, for a comparison of the results in these two groups in our entire series reveals no essential difference (table 2). Definite improvement was obtained in almost two thirds of the cases, and only about a fourth of the patients in each group required amputation. A viable, useful extremity was secured in 78.5 per cent of the 28 patients with impending gangrene and in 35 per cent of the 83 patients with frank gangrene. Transmetatarsal amputation, as described by McKittrick and co-workers,[4] was done in eight patients with salvage of the extremity in three. There were no operative deaths in the entire series.

Table 1.—*Results of Sympathectomy in Nondiabetic and in Diabetic Group*

	Nondiabetic				Diabetic			
Classification	No	Improved	Unimproved	Amputated	No	Improved	Unimproved	Amputated
No gangrene	63	53 (84.1%)	8 (12.7%)	2 (3.2%)	27	24 (88.9%)	2 (7.4%)	1 (7%)
Impending gangrene	19	15 (78.9%)	0	4 (21.1%)	9	7 (77.8%)	1 (11.1%)	1 (11.1%)
Frank gangrene	42	10 (23.8%)	4 (9.5%)	28 (66.7%)	41	19 (46.3%)	5 (12.2%)	17 (41.5%)
Total	124	78 (62.9%)	12 (9.7%)	34 (27.4%)	77	50 (64.9%)	8 (10.4%)	19 (24.7%)

Table 2.—*Total Results of Sympathectomies in Diabetic and Nondiabetic Groups*

Classification	No. of Sympathectomies	Improved	Unimproved	Amputated
Nondiabetic	124	78 (62.9%)	12 (9.7%)	34 (27.4%)
Diabetic	77	50 (64.9%)	8 (10.4%)	19 (24.7%)
Total	201	128 (63.7%)	20 (9.9%)	53 (26.4%)

COMMENT

In general, the results obtained in this series of cases are similar to those reported by others. Although no controls are available for purposes of comparison, it seems reasonable, on the basis of this experience and the determined effort to provide a critical evaluation of the results of therapy, to make certain observations and to draw certain conclusions concerning the value as well as the limitations of sympathectomy in arteriosclerotic peripheral vascular disease. Certainly all our previous experience, as well as that of others, has indicated that amputation is almost invariably required in impending as well as frank gangrene and that deaths were by no means unusual. Indeed, 10 to 12 years ago the mortality rate after amputations ranged from approximately 15 to 30 per cent.[5]

Much more impressive results probably could have been obtained had we continued to employ sympathectomy as we employed it originally, that is, in carefully selected cases. With increasing experience, however, the indications for operation were broadened. It was found that even after frank gangrene had developed sufficient improvement in circulation might be achieved to secure arrest of the process with complete healing and minimal loss of tissue and that if amputation should be necessary, a functioning extremity might be preserved because of use of a less radical operation.

Age.—Age is no longer considered a contraindication to sympathectomy. Almost 60 per cent of our patients were 60 years of age or over, and 15 per cent were more than 70 years of age. Sympathectomy, however, is perhaps less frequently indicated in the elderly because they are more liable to have other more disabling disturbances. In those patients already incapacitated by cardiac or other disorders the relief from peripheral vascular symptoms which might follow sympathectomy would be insignificant unless there were pressing indications for surgical therapy, such as constant intractable pain, progressive infection or gangrene.

Bilateral Operation Preferable.—Although symptoms usually appear first on one side, the arteriosclerotic process generally involves the vessels of both lower extremities. For this reason and because an additional burden may be subsequently placed on the apparently symptomless extremity, we have come to believe that the operation should be done bilaterally unless there is some definite contraindication. The operating time is not prolonged significantly, and the additional risk of a subsequent anesthetic and operation is avoided. In the patients treated in this manner and followed for long periods it has been gratifying to observe the paucity of symptoms in the prophylactically treated extremity.

Good Results in Diabetics.—The high incidence of good results and the definite improvement in circulation which has followed sympathectomy in the diabetic patients would suggest that it is a particularly useful procedure in these circumstances. McKittrick [5b] among others has emphasized the value of prompt attention to infections of the feet and the careful performance of minor amputations in the management of these patients. Our experience leads us to believe that in many of these patients with localized infections of gangrenous processes sympathectomy provides sufficient improvement in the circulation to permit greater ease in control of infection and rapid arrest of the ischemic process with complete healing and minimal loss of tissue. It would also appear to reduce the incidence of subsequent major amputation.

Sympathetic Block.—In our early experience with sympathectomy a good deal of reliance was placed on the use of sympathetic block as a preliminary procedure to test the value of sympathectomy, but with increasing experience we soon realized, as did others, that this is not an entirely dependable test in this type of peripheral vascular disease. Vasospasm is not always a prominent factor in degenerative arterial disease, and the maximum effects of interruption of the sympathetic pathways for the production of vasodilatation require a much longer period than can be secured by temporary sympathetic block. Numerous patients have been observed in whom little or no immediate vasodilatation followed the block but in whom sympathectomy was followed by gradually increasing improvement in the circulation which reflected slowly developing vasodilatation and collateral circulation. Perhaps the one group of patients in whom the test may be useful in determining the value of sympathectomy is that with severe, intractable pain or ischemic neuritis. In these circumstances if a properly performed block provides no relief of pain it is doubtful that the sympathectomy will be any more effective.

Gangrene.—Several observers [6] have directed attention to the occasional occurrence of gangrene after sympathectomy in patients with advanced occlusive arteriosclerosis. This has been explained on the basis of Popoff's [7] suggestion that arterial blood may be shunted from the capillary system directly into the veins through the opening up, as a consequence of sympathectomy, of the arteriovenous anastomoses described by Sucquet [8] and Hoyer.[9] On this basis and their experience with four cases of gangrene following sympathectomy, Freeman, Leeds and Gardner [6b] have expressed the belief that sympathectomy may be contraindicated in cases of severe obliterative vascular disease with low vasomotor tone or without evidence of abnormal vasoconstriction. These observers recognized, however, that this concept was still hypothetic and without adequate proof. As pointed out by Smithwick,[10] a study of these cases suggests that recent acute vascular occlusion had occurred and inadequate collateral circulation was present at the time of operation. Moreover, serious objections to this concept lie in the fact that the occurrence of gangrene following sympathectomy in cases of advanced obliterative arterial disease is relatively uncommon and in the fact that most of these patients have low vasomotor tone but often show slow but progressive improvement in circulation after sympathectomy. In our experience frank gangrene developed rather rapidly after sympathectomy in only one patient with impending gangrene. In this case, however, the history and short duration of symptoms suggested the occurrence of acute vascular occlusion with progressive thrombosis and inadequate collateral circulation. The operation, but not necessarily the sympathectomy per se, may have been an additional factor in furthering the occlusive and ischemic process.

Theoretical Objections to Sympathectomy.—In this connection it is pertinent to consider the theoretical objections to sympathectomy advanced from time to time and consisting in the belief, derived from certain experimental observations, that the resultant vasodilatation takes place in the skin and not in the muscle, and consequently that blood may be diverted from the muscles to the skin. As emphasized by Learmonth,[11] this hypothesis does not withstand investigation. For one thing, results of studies in man to determine blood flow in muscle and skin in these circumstances have been contradictory and inconclusive.[12] For another, this hypothesis does not conform to clinical experience. Intermittent claudication is not worsened by sympathectomy; it is usually benefited. Finally, it should be realized that the major threat in patients with arteriosclerotic peripheral vascular disease stems primarily from a deficiency in the cutaneous circulation. Impending or actual gangrene occurs first in the skin, not in the muscle. This is the major cause for amputation, not intermittent claudication. It is therefore apparent that in these circumstances improvement in blood flow through the skin assumes major importance, a fact which enhances rather than depreciates the value of sympathectomy.

Contraindications.—On the basis of this experience we believe that sympathectomy is the method of choice in the treatment of arteriosclerotic peripheral vascular disease unless definite contraindications to operation

exist. These include particularly severe cerebral, cardiac, renal or pulmonary involvement, a far advanced and rapidly progressive process, and pronounced atrophic changes in the limb. The presence of intractable pain or severe ischemic neuritis which cannot be relieved by sympathetic block should also be regarded as a contraindication. The most suitable subjects for sympathectomy are those with manifestations of the more slowly progressive forms of the disease with moderate degrees of involvement, but highly gratifying results may also be achieved even in patients with impending or actual gangrene, although not as frequently as in the former group.

Rationale and Value of Sympathectomy.—Finally, we believe that these observations provide additional support of the rationale and value of sympathectomy in arteriosclerotic peripheral vascular disease. As emphasized previously in a consideration of the rationale of sympathectomy in peripheral vascular disease, it must be regarded not as a direct attack on the cause of the disturbances but rather as a means of correcting or [illegible] the effects of the disease, which take the [illegible] in the circulation of the part.[1d] It is based on sound physiologic principles consisting essentially in the release of constrictor tonus, which may or may not be excessive, depending on the type and stage of the disease. By this means it permits maintenance of the maximum degree of vasodilatation in the denervated area, thus producing an increase in the volume of the local vascular bed and consequent improvement in the local circulation. In this respect the objective of the procedure conforms to the concept of hemodynamics to which the term hemometakinesia[1] has been applied and thus provides a further rational basis for sympathectomy. This concept is derived from certain observations concerning the physiologic features of the circulation which establish the presence of spontaneous and even rhythmic fluctuations in the volume of organs primarily attributable to changes in the volume of blood within the part These fluctuations of the blood volume in different parts of the body can occur without any alterations in the total blood volume or cardiac output by an adjustment of the vascular bed, which permits simultaneously an increase in the volume of blood (through vasodilatation) of one part of the body and a corresponding decrease (through vasoconstriction) elsewhere. This compensatory process, permitting the "borrowing and lending" of blood by various tissues to meet variations in requirements, is indicative of a well regulated mechanism designed to permit the body to utilize its limited total blood volume in the most efficient manner. The sympathetic nervous system plays an important role in this mechanism of control and regulation of the peripheral vascular bed. Interruption of the sympathetic pathways to the part removes the vasoconstrictor factor in this mechanism, resulting in maximum vasodilatation in the vascular bed of the affected part. Other means of producing such vasodilatation by the use of vasodilator agents administered systemically have long been attempted with little success. These agents for the most part produce transitory and varying degrees of generalized vasodilatation. In most peripheral vascular disturbances, however, the impairment in circulation is usually localized to one or two peripheral parts. Accordingly, the therapeutic effort should rationally be directed not toward the production of vasodilatation of the entire vascular bed but rather toward the production of local vasodilatation limited to the part in need of more blood. These are not alone theoretical considerations; they are supported by both clinical and experimental observations. Although some observers have reported favorable results following the use of certain generalized vasodilator agents, we have not been able to confirm these observations.[14] Indeed, our studies on peripheral blood flow conducted under controlled atmospheric conditions revealed that none of these vasodilator agents could consistently produce in a local peripheral part vasodilatation equal in degree and duration to that produced by sympathetic denervation of the part.[14] More recent reports have confirmed these observations.[15]

SUMMARY

1. An evaluation of the results of lumbar sympathectomy in the treatment of arteriosclerotic peripheral vascular disease is presented on the basis of 146 consecutive patients, 55 of whom had bilateral involvement. All patients were followed at least six months, three fourths of the patients more than one year and 38 per cent from two to four or more years. Results of therapy were evaluated at the end of the follow-up period.

2. The cases were divided into three categories, (1) no gangrene, (2) impending gangrene and (3) frank gangrene, according to the severity of involvement They were further subdivided into those with and without diabetes.

3. The best results were obtained in patients with the least severe disease, over 85 per cent showing definite improvement. A gratifying incidence of improvement was also achieved among more than three fourths of the patients with impending gangrene. Even among the patients with frank gangrene definite improvement with salvage of the extremity was secured in 35 per cent of cases. A comparison of the results among the diabetic and nondiabetic groups revealed no essential difference except in the category of frank gangrene, in which a somewhat higher incidence of improvement was observed among the diabetic patients. There were no operative deaths in the entire series.

4. Sympathetic block as a preliminary procedure to test the value of sympathectomy is not an entirely dependable test, except perhaps in patients with severe intractable pain or ischemic neuritis.

5. Sympathectomy is considered the method of choice in the treatment of arteriosclerotic peripheral vascular disease unless there exist definite contraindications to operation, such as severe cardiac, cerebral, renal or pulmonary involvement, a far advanced and rapidly progressive process, and pronounced atrophic changes in the extremity.

SHAKESPEARE'S KNOWLEDGE OF CHEST DISEASES

Chairman's Address

WALTER E. VEST, M.D.
Huntington, W. Va.

One of the most zealous students of the Bard of Avon, Mary Cowden Clarke, says that the brightest ornament of the British nation is the genius of Shakespeare. Probably everyone will admit that he was one of the greatest geniuses the Anglo-Saxon race has ever produced, if not the greatest. His grasp of the details of all phases of knowledge and of life is astounding. As far as is known he never studied medicine, but his comprehension of medicine and disease compares favorably with that of his physician contemporaries, who were none too well versed in scientific medicine themselves. The poet's medical knowledge must be viewed, however, in the light of the actual medical knowledge and practice prevalent among the physicians of his day. Licensure had just been introduced, and medicine was indeed embryonic. Harvey first mentioned to his students his ideas of the circulation during the week of Shakespeare's death and published the details of his immortal discovery 12 years later.

Probably the knowledge of chest diseases was less advanced around the beginning of the seventeenth century than was medicine generally. Certainly Shakespeare's references to chest conditions are fewer than to almost any other group of diseases. He does, however, make many references which are of interest to chest specialists.

The lungs are referred to 19 times in the plays and twice in "A Lover's Complaint." In addition to mention of the respiratory function of the lungs, there are five instances that relate them to mirth and laughter. For instance, when Alonzo upbraids Gonzalo for describing his impossible utopia, the latter replies, "I . . . did it to minister occasion to these gentlemen, who are of such sensible and nimble lungs that they always use to laugh at nothing" (Tempest, II, i). And Armado says, "The heaving of my lungs provokes me to ridiculous smiling." (Love's Labor's Lost, IV, i). Also, the melancholy Jaques, after reciting the fool's comments on the dial and the aging process, says:

> When I did hear
> The motley fool thus moral on the time,
> My lungs began to crow like chanticleer,
> That fools should be so deep-contemplative,
> And I did laugh sans intermission
> An hour by his dial.
>
> *As You Like It,* II, vii.

Contrariwise, another reference suggests that sorrow and regret may be pulmonary in origin: "Hallowed with sighs that burning lungs did rise" (Lover's Complaint, line 228).

There are five references which imply that speech is in part a function of the lungs, as: "My lungs coin words" (Coriolanus, III, i), or, as when the host of the Garter Inn calls to Falstaff, "Bully Sir John! Speak from thy lungs" (Merry Wives of Windsor, IV, v).

Eight instances seem to refer to pulmonary physiology or, rather, pulmonary pathology, as: "Lungs and rotten ones" (Tempest, II, i), "Wheezing lungs" (Troilus and Cressida, V, i), "Infected lungs" (Pericles, IV, vi) and "That sad breath his spongy lungs bestow'd" (Lover's Complaint, line 326).

That the poet comprehended the possibility of pneumonia as a complication of measles is evident in:

> So shall my lungs
> Coin words till their decay against those measles
> Which we disdain should tetter us!
>
> *Coriolanus,* III, i.

The dyspnea incident to approaching death is evident when Henry IV on his deathbed says:

> My lungs are wasted so
> That strength of speech is utterly denied me.
>
> *2 Henry IV,* IV, v.

Shakespeare knew the condition we call asthma. We have already mentioned "wheezing lungs," which, from the context in this instance, he must have believed to be a symptom of syphilis. Also, he uses the term "tisick" when Pandarus says, "A whoreson tisick, a whoreson rascally tisick so troubles me . . . that I shall leave you one of these days" (Troilus and Cressida, V, iii).

Thomas Elyot, in the "Castelle of Helthe" (1534), uses "tisick" as synonymous with "shortnesse of breth." Onions defines it here as "a consumptive cough" and Schmidt as asthma or possibly "hectic." In the southern Appalachians, the laity still speak of asthma as "phthisic." Careful study of the context convinces me that Shakespeare actually meant asthma and that he probably believed it to be syphilitic in origin, for Pandarus goes on to say, "I have . . . such an ache in my bones that . . . I cannot tell what to think on't" (Troilus and Cressida, V, iii).

Cough is mentioned seven times, but in only two instances is it clear as a part of the symptom complex. In one it is a manifestation of the common cold, the contagiousness of which is also implied. When Falstaff is examining his recruits in Gloucestershire, this dialogue takes place:

> BULLCALF: I am a diseased man
> FALSTAFF: What disease hast thou?
> BULLCALF: A whoreson cold, sir, a cough, sir, which I caught . . . upon . . . coronation day.
>
> *2 Henry IV,* III, ii.

In the second instance, cough is represented as a part of the aging process. Ulysses, in "Troilus and Cressida" (I, iii), lists "to cough and spit" among "the faint defects of age."

Consumption is mentioned five times, and severity and wasting are always implied. Falstaff likens his pecuniary condition to consumption thus, "I can get no remedy against this consumption of the purse; borrowing only lingers and lingers it out, but the disease is incurable" (2 Henry IV, I, ii).

Once the word is used as synonymous with "plague" and as part of a curse: "Consumption catch thee!" (Timon of Athens, IV, iii). Here, spoken by Timon, the word may refer to syphilis, for earlier in the same scene he uses the plural "consumptions," unquestionably descriptive of late syphilis; and, incidentally, here is the first reference to the sunken nose of syphilis, as far as I can determine, in medical or any other type of literature. Lear, in his maniacal raving, names consumption as one of the attributes of "hell . . . the sulphurous pit" (King Lear, IV, vi). Consumption, in the modern sense of pulmonary tuberculosis, is used

---

Read before the Section on Diseases of the Chest at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 28, 1950.

tauntingly by Beatrice to her sweetheart, Benedick, when she agrees to accept his suit and become his bride: "I yield upon great persuasion, and partly to save your life, for I was told you were in a consumption" (Much Ado About Nothing, V, iv). It would appear here that Shakespeare believed pulmonary tuberculosis curable, an idea decidedly advanced for medicine of that day.

While the word "spit" is used often in the plays, in only two instances does it have a medical implication. We have already mentioned that the characteristics of aging, as listed by Ulysses, include "to cough and spit," probably referring to the bronchiectatic aged. In the second instance, Falstaff says, "I would that I might never spit white again." The reference here is to the fact that physicians then regarded the color of the sputum as especially diagnostic of temperaments. Dark sputum was, according to Batman, "of melancholy," and "the white spettle not knottie, signifieth health." Some believed that white spittle was due to thirst, and Nares held that "to spit white" was a result of alcoholic intemperance. Falstaff's known inebriety, considered with the context, would lead us to the conclusion that Falstaff, at least, concurred in this opinion. "Hawking and spitting" is used in one instance, but as a manifestation of emotional embarrassment rather than with disease significance.

"Rheum" is used 15 times in the plays, most often in the sense of tears. When Shylock says to the would-be borrower Antonio, "you . . . spet upon my Jewish gaberdine" and "did void your rheum upon my beard," the word evidently means saliva. Once it is used in the sense of a nasal discharge, but in no instance does the poet use rheum in the modern medical sense of sputum.

"Plurisy" is used once, or, if we accept the opinion of Dyce, Lamb and Coleridge that Shakespeare actually was co-author with Fletcher of the "Two Noble Kinsmen," twice. In each instance the word is used in the sense of "plethora" rather than of an inflammation of the pleural membrane. In fact, "plurisy" was most commonly used in the former sense three centuries ago. More likely the condition we now know as pleurisy is meant when Prospero says:

> Tonight thou shalt have cramps,
> Side-stitches that shall pen thy breath up.
>
> *Tempest,* I, ii.

"Catching cold" in the sense of contracting an acute respiratory infection, or what we now call the common cold, is referred to 10 times. The idea, still prevalent among the laity, that to lie down without covering may usher in an acute cold, is seen in: "Yet here they shall not lie, for catching cold" (Two Gentlemen of Verona, I, ii).

We have already noted the idea of contagiousness of colds in the dialogue between Falstaff and the recruit, and weather as a causative factor is implied when the diminutive Grumio says, "Considering the weather, a taller man than I will take cold" (Taming of the Shrew, IV, i). Later in the same scene, after exposure to cold, he says, "I have caught extreme cold." Even the fool in "King Lear" implies that the weather is a causative agent when he says, "As the wind sits, thou'lt catch cold shortly" (King Lear, I, iv). The possible severity of the common cold is alluded to when Hotspur says, " 'Tis dangerous to take a cold" (1 Henry IV, ii). Knowledge of the sensation of nasal constriction and stuffiness and the disturbance of the sense of smell, as symptomatic of a head cold, is displayed when Hero calls attention to the "excellent perfume" of the gloves given her by the count:

> Beatrice: I am stuffed, cousin; I cannot smell.
> Margaret: . . . There's goodly catching of cold.
>
> *Much Ado About Nothing,* III, iv.

The high diaphragm in the corpulent person is alluded to when Prince Hal says to Falstaff, "This bosom of thine . . . is all filled up with guts and midriff" (1 Henry IV, III, iii). The term midriff was commonly used by the profession in middle and early modern English instead of diaphragm.

The grave illness of the King of France, whose recovery had been despaired of, was described by Shakespeare in "All's Well That Ends Well" as a fistula, a term then implying a discharging sinus anywhere in the body. From Boccaccio, the source of the plot, we know, however, that the actual condition was a draining chest sinus, a sequela of an empyema necessitatis. The King's condition had resisted all treatment given by the medical profession when Helena, the daughter of Gerard de Narbon, a "physician . . . much fam'd," offered to effect a cure by means of a secret prescription originated by her father. In those days surgeons were accustomed to keep their remedies secret, but physicians preferred to share their knowledge with their confrères. The King shows his knowledge of the medical ethics of his time and of the attitude of the profession in his reply to the girl's proffer of treatment:

> We thank you, maiden:
> But may not be so credulous of cure,
> When our most learned doctors leave us; and
> The congregated college have concluded
> That laboring art can never ransom nature
> From her inaidable estate; I say we must not
> So stain our judgment, or corrupt our hope,
> To prostitute our past-cure malady
> To empirics, or to dissever so,
> Our great self and our credit, to esteem
> A senseless help which help past sense, we deem.
>
> *All's Well That Ends Well,* II, i.

But Helena will not be refused. She argues and promises that if he is not cured within eight days she will forfeit her life "with vilest torture." Finally the King consents, saying:

> "Sweet practiser, thy physic I will try,
> That ministers thine own death if I die."
>
> *All's Well That Ends Well,* II, i.

Helena's prescription most miraculously cures him in two days, to the amazement of "the learned and authentic fellows," followers of both "Galen and Paracelsus . . . that gave him out incurable" and "not to be helped."

While tuberculosis of the cervical lymph nodes, or scrofula, is not, strictly speaking, a chest disease, it is of interest to chest specialists because its etiology makes it a part of the over-all problem of tuberculosis. Shakespeare knew the condition as "king's evil," so named because of the belief that its victims were cured after having had their lesions touched by the reigning sovereign. The disease is alluded to in only one play, "Macbeth," and this scene was probably introduced as a compliment to James I, who had recently come to the throne and had revived the custom of "touching," believing himself hereditarily endowed with the alleged miraculous powers of Edward the Confessor, the first to claim the "curative touch." James is said to have been especially proud of exercising the "touching power." Wilkes quotes Sir William Davenant (certainly the godson of Shakespeare and reputedly his illegitimate son) as saying that "in recognition of this fulsome compliment [in "Macbeth"], King James sent Shakespeare a letter of acknowledgment in his own handwriting."

While Malcolm and MacDuff are discussing the woes of Scotland and the misgovernment and crimes of Macbeth, a physician enters. Malcolm questions the man of medicine:

Comes the king forth, I pray you?
  Doctor: Ay, sir; there are a crew of wretched souls
That stay his cure. Their malady convinces
The great assay of art; but at his touch,
Such sanctity hath heaven given his hand,
They presently amend.
  Malcolm: I thank you, doctor.
  MacDuff: What's the disease he means?
  Malcolm: 'Tis called the evil;
A most miraculous work in this good king,
Which often, since my here-remain in England,
I have seen him do. How he solicits heaven,
Himself best knows; but strangely-visited people,
All swollen and ulcerous, pitiful to the eye,
The mere despair of surgery, he cures,
Hanging a golden stamp about their necks,
Put on with holy prayers; and 'tis spoken,
To t' [illegible] he leaves
The [illegible] With this strange virtue,
He hath a heavenly gift of prophecy,
And sundry blessings hang about his throne,
That speak him full of grace.

Macbeth, IV; iii.

The solicitation of heaven was evoked by the monarch in the "touching" ceremony, which was very solemn and impressive. The church dignitaries stood by. The king touched the diseased glands of the patient and solemnly intoned, "Rex tangit te; Deus sanat te, in nomine Patris et filii et spiritus sancti." The golden stamp alluded to by Shakespeare was here an anachronism, for the early kings gave only a penny as a neckpiece, but Henry VII in 1505 introduced the practice of giving a golden coin, called an angel, the value of which was 6s. 8d., or about a dollar at our present rate of exchange, although the purchasing power of money then was probably at least 25 times that of the present. It is a matter worthy of note that the angel was a coin in common circulation in the Elizabethan era and was the physician's usual fee for a consultation.

The superstition of the "royal touch" was well grounded in England. Pope Alexander III canonized Edward the Confessor and recognized his miraculous gift of healing. For years the "touching" service was a part of the Book of Common Prayer, but it was expunged in 1719.

I have discussed the medical references of interest to chest specialists as found in the work of Shakespeare and have endeavored to show that he understood medicine as it was known and practiced in his day and that in at least one instance, as to the curability of pulmonary tuberculosis, his thinking was well in advance of that of his physician contemporaries. He was not a physician in the strict sense of the term, but he knew and portrayed medicine in the way that he knew and portrayed all nature and all life—as its master. To quote Sir St. Clair Thomson, "His profound knowledge of human life and human nature . . . explains why he is, and must always be, one of our greatest masters of medicine."

REFLECTIONS ON THE CAUSATION OF DIABETES MELLITUS

The Frank Billings Lecture

RUSSELL M. WILDER, M.D., Ph.D.
Rochester, Minn.

My interest in diabetes began with a residency at the Presbyterian Hospital of Chicago, to which I was appointed by Dr. Billings. The Sprague Memorial Institute had been founded not long before at Dr. Billings' instigation and was supporting the research of Dr. Woodyatt. My days were divided equally between the hospital and Dr. Woodyatt's laboratory. As I recall that period, there was no uncertainty then about the cause of diabetes. It had been shown by von Mering and Minkowski[1] that ablation of sufficient pancreatic tissue would provoke diabetes in the dog. It was known from the work of Allen[2] and of Homans[3] that degeneration of the islets in the pancreatic remnant of partially depancreatized dogs was followed by development of diabetes, and it had been observed by Opie[4] that the islets of the pancreas of diabetic patients were frequently abnormal when examined after death. Diabetes mellitus was pancreatic diabetes in those days. In contrast, the subject of the origin of the disease now is enveloped in confusion. In the minds of some authorities, the pancreas has been deposed from its prime position in causation, and diabetes, formerly considered a clinical entity, has been degraded to a syndrome with multiple causes. The pioneer discoveries of Houssay and his colleagues,[5] followed by the work of many others, is responsible for this new point of view, although few of those responsible may share it. Their experiments have revealed that pancreatic diabetes is alleviated by removal of certain organs, notably the pituitary body, the adrenal cortices and the thyroid gland; and furthermore that conditions resembling diabetes are producible experimentally by injection of hormonal products of these organs.

It now has been established that regulation of the blood sugar level is a complex process in which several of the endocrine glands, together with the central nervous system, are engaged. In a mechanical analogy of blood sugar regulation Soskin and Levine[6] (fig. 1) place the liver in the center of the stage, the liver being acted on in one direction (producing hyperglycemia) by the anterior lobe of the pituitary body, the adrenal cortex and the thyroid and in the opposite direction (producing hypoglycemia) by the pancreas. In another diagrammatic representation of the balance between hypoglycemic and hyperglycemic factors McQuarrie and co-workers[7] (fig. 2) picture a beam and scales

Pancreatic beta cells produce insulin and weight the beam in one direction to cause hypoglycemia. The pituitary body, the adrenal glands, the thyroid, the liver and the diet weight the beam in the opposite direction, possibly assisted by the ovary and a hyperglycemic hormone originating in the pancreatic alpha cells. Stimulation of several of these opposing forces is by the parasympathetic or the sympathetic nerves, which may place the ultimate control of the process with the central nervous system.

As well established as is this multiple control of blood sugar regulation is the fact that preexisting diabetes is profoundly modified by the activity of these insulin opponents. In particular, overfunction of the hypophysis, the adrenal cortices and the thyroid gland leads to aggravation and their underfunction to amelioration of the diabetes.

However, it is not so well established that the hypophysis, the adrenals or any of the insulin antagonists are primarily responsible for diabetes in man, for human diabetes is something more than mere displacement of the level of blood sugar. Permanent derangement of the normal homeostasis is a basic characteristic. "Once a diabetic, always a diabetic" is a maxim to which exceptions are extremely rare, and permanence, as I shall show, is rarely a characteristic of so-called pituitary or adrenocortical diabetes, or of any form of hyperglycemia, except that with which the pancreas is involved.

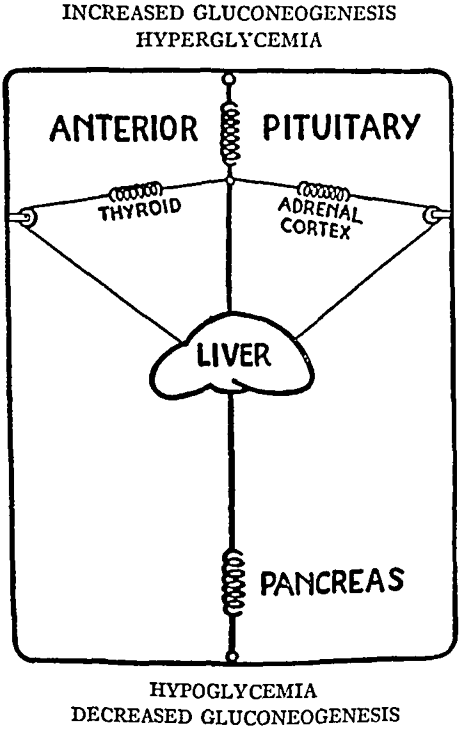

Fig. 1.—Mechanical analogy of carbohydrate metabolism (from Soskin and Levine [6]).

FORMS OF HYPERGLYCEMIA

I shall briefly review the types of hyperglycemia of diverse nonpancreatic origin to observe wherein they differ from the hyperglycemia of human diabetes. One must bear in mind while doing this that both in transient hyperglycemia of whatever origin and in what I am calling the permanent hyperglycemia of human diabetes one is not concerned with the blood sugar level at any particular moment. What is of interest is the permanence of the displacement of the balance. In any type of hyperglycemia the concentration of blood sugar at any moment may be lowered by altering the diet or by administering insulin.

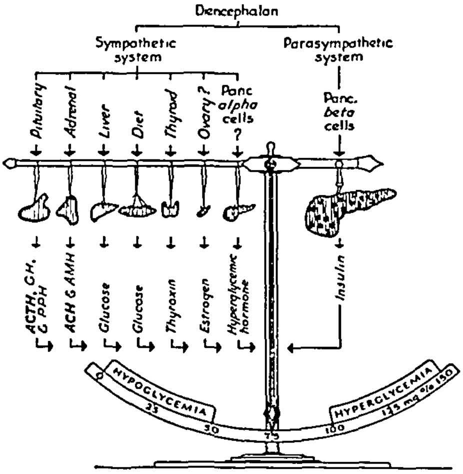

Fig. 2.—Schematic representation of balance between hypoglycemic and hyperglycemic factors affecting carbohydrate metabolism (from McQuarrie, Bauer, Ziegler and Wright [7]). The initials ACTH, GH, PPH, ACH and AMH denote pituitary adrenocorticotropic, gonadotropic, posterior pituitary, adrenocortical and adrenal medullary hormone (epinephrine), respectively.

Toxic Hyperglycemia.—Hyperglycemia with or without glycosuria is met with on occasion in almost all infections, especially at the height of fever. It also may be seen in some intoxications. The transitory nature of such hyperglycemia is a matter of common knowledge. It seldom is confused with diabetes. However, there are two exceptions: the pancreatitis which accompanies mumps can lead to permanent diabetes; so also may the poisoning of an animal with alloxan. However, in both these instances the diabetes is pancreatic diabetes, being dependent on a degree of injury of the insulogenic beta cells of the pancreatic islets.

Neurogenic Hyperglycemia.—At times after the brain has been injured by accident, tumor or operation high values for blood sugar are encountered and glycosuria may be intense. Such hyperglycemia depends on the presence of preformed glycogen in storage in the liver, although at times an alarm reaction is involved with participation of the pituitary-adrenal axis. In any case, these types of hyperglycemia are transitory and seldom are diagnosed as diabetes. It was not so always. Bernard,[8] one hundred years ago, believed that he had produced true diabetes mellitus by his puncture of the floor of the fourth ventricle, and so weighty was his influence that from then until the production of pancreatic diabetes by von Mering and Minkowski [1] many clinical observations of the relationship of diabetes to lesions of the pancreas were disregarded.[9] The mechanism of the effect of the Bernard procedure is still a puzzle. The nerve impulse initiated by his puncture follows the sympathetic nerves and not the vagus nerves, as he himself was the first to demonstrate. Participation of the adrenal medulla was suspected at one time, but this is not essential, because ablation of both adrenal glands will not prevent the effect. The suggestion has been made that a sympathin is liberated elsewhere, perhaps even in the liver, thereby releasing the glycogen in storage in the liver. In any case, the effect can only be observed when preformed glycogen is on deposit in the liver, and no one today regards such neurogenic diabetes as diabetes mellitus.

Injected epinephrine provokes hyperglycemia when the liver contains glycogen, and hyperglycemia sometimes results from spontaneous liberation of epinephrine by tumors of the adrenal medulla (pheochromocytomas). These tumors are very rare; sugar is not always seen with them, and, when it occurs, it disappears with almost no exceptions when the tumor is removed.

Hunger Hyperglycemia.—Hyperglycemia with glycosuria may develop when fasted or semifasted persons are fed with carbohydrate. The phenomenon has been called "hunger," "famine" or "vagabond" diabetes. The response to a glucose tolerance test encountered in a normal subject who has fasted, or whose diet has been high in fat and low in carbohydrate, is a prolonged high blood sugar curve like that which in other circumstances suggests the presence of pancreatic diabetes. In point of fact, this is a form of pancreatic diabetes. It is correctable, however, simply by continuing to feed a diet which is normal with respect to carbohydrate and so is incorrectly diagnosed as diabetes. I observed the same phenomenon when a nondiabetic person was given insulin for a period of days.[10] The most reasonable explanation of the phenomenon is that the cells of the pancreatic islets which manufacture insulin, the so-called beta cells, are lulled into somnolent inactivity either by fasting or by giving insulin and thus, like the "five foolish virgins," find themselves with empty lamps when called. This explanation is supported by histologic studies which reveal fewer negative Golgi images than normal and a paucity of granulations in the beta cells of fasted animals.[11] Furthermore, the amount of insulin recoverable from the pancreas of animals fed little carbohydrate or given insulin has been found to be low.[12]

Thiamine Deficiency.—Hyperglycemia and glycosuria are encountered in beriberi and in experimental thiamine deficiency in man. The fault here is with the utilization of the intermediates having 3 carbon atoms, lactate and pyruvate. This probably effects a degree of retardation of the rate at which dextrose is removed from the blood. The abnormality is correctable with thiamine, which may explain in part the improvement of presumed diabetes occurring in some patients with dysfunction of the liver who are receiving treatment for their hepatic abnormality with vitamins, including thiamine.

Hepatic Hyperglycemia.—Reports[13] that many diabetic patients give evidence of dysfunction of the liver must relate to a different kind of diabetes than is encountered in the Mayo Clinic,[14] where, when patients with cholecystitis and other inflammatory conditions also involving the pancreas are excluded, dysfunction of the liver is uncommon. Likewise, Harold Brown,[15] in a recent study of 25 diabetic persons by means of a battery of liver function tests, obtained no evidence of impaired hepatic function. Fifteen of the patients had been through an episode of acidosis. Furthermore, neither cirrhosis nor hepatitis, when present, has influenced unfavorably the severity of the diabetes. The reverse is to be expected. Hepatic damage, if extensive, provokes a low concentration of blood sugar. Sometimes patients with hepatitis or cirrhosis will have sugar in their urine after meals although their levels of blood sugar before the first meal of the day are normal, low or occasionally very low. There is no evidence to show that utilization of glucose is abnormal in these cases; the fault is with the glycogen warehouse. It is generally agreed that such conditions are incorrectly diagnosed as diabetes mellitus. The diabetes which accompanies hemochromatosis is an exception. The pancreatic islets are injured as much as is the liver in hemochromatosis.

Without the liver sugar cannot be made from protein or other glucose formers. In the absence of the liver the supply of sugar is cut off; therefore, in the fasting animal a degree of hepatic function is a necessary condition for the development of glycosuria. In pancreatic diabetes glycogen formation is disturbed and the rate of gluconeogenesis is increased, but these abnormalities result from insufficiency of insulin and are at once correctable by giving insulin. Glycogenolysis, that is, liberation of preformed glycogen from the liver with resulting transient hyperglycemia, is provoked, as I have said, by toxic and neurogenic irritants of the liver; also, as I shall point out, the rate of gluconeogenesis may increase in response to overfunction of the pituitary-adrenal axis. However, in my opinion this provides insufficient grounds for assuming that the liver is able independently, permanently and continuously to increase the rate at which it manufactures sugar.

Pituitary Hyperglycemia.—The statement frequently has been made that glycosuria occurs in a large proportion of all cases of acromegaly.[16] This is not confirmed by experience at the Mayo Clinic. The incidence of diabetes mellitus in the cases of acromegaly has been relatively low, less than 9 per cent,[14] and the diabetes in half of these cases clearly antedated the disease of the pituitary body. The diabetes usually was mild when the two diseases were associated, but, mild or severe, it usually disappeared, as in examples cited recently by Balfour and Sprague,[17] when the disease of the pituitary body either burned itself out, as frequently happens, or was corrected by operation or other treatment. I interpret this small incidence of acromegalic diabetes and its transitory nature when it does occur as meaning that the pituitary growth hormone—effective as this may be experimentally in provoking diabetes in certain animals[18]—is produced in amounts which are insufficient even in acromegaly to provoke true diabetes mellitus in the otherwise normal man.

At least two so-called diabetogenic products have been obtained from beef pituitary body. Recently a third product, prolactin, has been found to have similar activity.[19] The first of the two diabetogenic products obtained appears to be identical with the growth hormone previously considered. The second is pituitary adrenocorticotropic hormone (ACTH). When the adrenocorticotropic hormone is administered in large amounts to rats it provokes the adrenal cortices to hyperplasia and overfunction with resulting hyperglycemia and glycosuria.[20] Also, when administered to man in sufficient quantities and for a sufficient length of time, this hormone has elicited a "temporary diabetes."[21] The effect in man, however, appears to be inconstant; during the past eighteen months or so pituitary adrenocorticotropic hormone or the adrenocortical hormones themselves have been used in the treatment of a considerable number of patients with several diseases, but relatively little evidence of production of a diabetic type of abnormality has been encountered. The values for the fasting blood sugar of these patients almost always have been normal. In 1 case hyperglycemia with glycosuria developed but disappeared while injections of pituitary adrenocorticotropic hormone were continued The experience related is based on doses which, although small when compared with those inducing diabetes in the rats, were large enough, 100 mg. a day, to elicit in one patient or another one or more of nearly all the other signs and symptoms of Cushing's syndrome.[22] From these observations I am led to the conclusion that the pituitary body, either through its growth hormone or through adrenocorticotropin, plays an exceedingly minor part in the pathogenesis of human diabetes In saying this I am not unmindful of reported observations on the size of some infants of diabetic women and on the stature of some diabetic children at the time of onset of their diabetes. Such observations seem to me to be irrelevant, because, if the pituitary bodies are overactive in these women or these children, other evidence of such activity should be available, but it is not. Furthermore, overfunction of the pituitary body is conceivable only when the function of its target organs (thyroid, adrenal cortices and so forth) is suppressed. These are self-limiting systems, and overfunction of the target organs puts a brake on pituitary function much as extension of the arms of the governor of a steam engine, when the extension reaches a certain limit, shuts off the steam. The simile was suggested to me by Dr. F. D. W. Lukens.

Adrenocortical Hyperglycemia.—The adrenocortical hormones, compound E (17-hydroxy-11-dehydrocorticosterone), now known as cortisone, and its chemical relation, compound F (17-hydroxycorticosterone), will themselves produce a form of diabetes when administered to animals or men. This diabetes, like that which follows injection of pituitary adrenocorticotropic hormone and that observed in patients with Cushing's syndrome, differs in the following important respects from diabetes mellitus: 1. It is highly resistant to insulin. 2. It is accompanied with azoturia (excretion of nitrogen in excess of intake), which continues even when there is no acidosis or at times when, because of dieting, the sugar in the urine is minimal or absent. This behavior is in sharp contrast with that of pancreatic diabetes. 3. In sharp contrast also is an increase in the glycogen in the liver.[23] 4. Corticoid diabetes responds to fasting much more promptly than does diabetes mellitus. A day of fasting will clear the urine of sugar in cases in which the glycosuria has resisted control with as much as 100 units of insulin or more. 5. With rare exceptions, corticoid diabetes is accompanied with some other evidence of adrenocortical hyperfunction, that is, symptoms or signs of Cushing's syndrome or the presence in the urine of greater than normal amounts of corticosteroids. My colleagues, Mason and Sprague, reported the isolation of 191 mg. of crystalline compound F from a 25-day collection of urine of one patient with hyperplasia of his adrenal cortices.[24] This contrasts sharply with the relatively normal excretion of these substances in diabetes mellitus. 6. The hyperglycemia is transitory in the sense that the blood sugar levels return to normal when the adrenocortical hyperfunction is corrected.

Thyrogenic Hyperglycemia.—A small proportion of patients with hyperthyroidism who previously have not been diabetic excrete sugar in small amounts and respond to glucose tolerance tests with high blood sugar curves. In part, this is explained by an increase in the rate of absorption of glucose from the bowel, a characteristic of hyperthyroidism, but this alone is not responsible, for dextrose given by vein at timed rates is utilized by hyperthyroid patients less rapidly than by normal persons.[25] The fault appears to lie in the rate of glycogen formation. In any case, unless a degree of diabetes existed before the onset of the hyperthyroidism, the disturbance is corrected when the thyroid status is restored to normal; hence, this form of hyperglycemia is not to be confused with that of diabetes mellitus.

META DIABETES

The term "meta diabetes" was introduced by Houssay[26] to describe a permanent diabetes which is produced in animals by stresses sufficient in intensity and duration to cause permanent damage to the pancreatic beta cells. Thus metahypophysial diabetes was provoked by Young[27] in adult dogs first with crude pituitary extracts,[27] later with purified growth hormone.[18b] When such extracts are injected into suitable animals, the early changes in the pancreas are identical with those obtained when dogs from which the pancreas has been partially ablated are overfed [2] or when glucose is administered to cats.[28] The beta cells show signs of exhaustion manifested by progressive degranulation, which proceeds to hydropic degeneration; likewise, the insulin content of such a pancreas is diminished until it reaches a tenth or less of normal values.[29] When in such experiments the injections of pituitary extracts are discontinued before they have led to these extreme disturbances, the beta cells regenerate and the pancreas regains its normal insulin content.[30] Only when the damage to the beta cells has been sufficiently severe does regeneration fail. In that case, the diabetes which ensues, like all true pancreatic diabetes, is characterized by permanence.

[27] Young, F. G: Permanent Experimental Diabetes Produced by Pituitary (Anterior Lobe) Injections, Lancet **2**: 372 374 (Aug. 14) 1937 Young[1b]

Clinical examples of permanent hyperglycemia of this meta type (metahypophysial, metaadrenocortical or metathyroid diabetes, which are examples of permanent diabetes in man secondary to overstimulation from the pituitary body, the adrenal cortex or the thyroid) have as yet not come to my attention. They may occur, but before such a diagnosis is permissible evidence must be presented to show that the patient was not previously diabetic. In the large majority of all cases of acromegaly, Cushing's syndrome or hyperthyroidism little hyperglycemia develops even temporarily, and a normal carbohydrate tolerance returns when the endocrine abnormality has been corrected. This necessitates the conclusion that the normal pancreas possesses the reserve capacity required to meet the overload imposed by these diseases and that normal beta cells have sufficient endurance to escape lasting damage from such stresses.

Obesity and Diabetes.—A form of clinical diabetes to which the designation "meta" applies quite forcibly is that which develops in obesity, representing, I should guess, about 80 per cent of the diabetes observed in adult patients. If it is true that insulin is used to turn glucose into fat, as recent evidence has suggested, the mere existence of obesity may be regarded as an index of pancreatic overload. In any case, the large amount of food which the fat man must consume to attain and maintain his excessive body weight imposes a metabolic stress which creates increased demand for insulin. This stress or overloading may not be severe but it always is of long duration, years on years; hence, in time the beta cells if they originally and presumably genetically are under par can be expected to degenerate, causing lasting diabetes. In the early stages of this type of diabetes, as is true of experimental pituitary hyperglycemia, damage to the pancreas is reversible; when some patients are reduced in weight to an appropriate degree of slimness their diabetes sometimes disappears to the point that the response to a sugar tolerance test is like that of normal persons. However, if such patients regain their former weight their diabetes returns; indeed, it not infrequently returns even if they do not gain any weight. However, diabetes develops in only a rather small minority of the total number of obese persons. Therefore it is safe to say that in cases in which it does develop, the patients started life with something less than normal insular endurance.

COMMENT AND CONCLUSIONS

This review of hyperglycemia of diverse origin has revealed that only when an abnormality of carbohydrate metabolism is characterized by permanence does it resemble human diabetes, which when once acquired is not lost; the maxim "once a diabetic, always a diabetic" holds true almost without exceptions. However, permanence which is a characteristic of human diabetes is observed only in those forms of experimental hyperglycemia which involve destruction of the pancreatic beta cells. These cells in man are sometimes injured by infection of the pancreas, by malignant disease of the pancreas or by hemochromatosis. Alloxan, which chemically is an oxidation product of uric acid, produces necrosis of the beta cells, and uric acid has been said to do the same in animals.[31] This gives rise to speculation about a possible relationship between gout and diabetes. However, association of gout with diabetes is exceedingly rare as is also the association of hyperuricemia without gout.

The beta cells of intact animals may be permanently injured by creating a demand for their incretion of such intensity that it leads to their exhaustion. Demands of this degree have been provoked experimentally by giving glucose intraperitoneally to cats [28] and by long-continued injection of pituitary extracts into adult dogs. In these instances the permanent diabetes which results, so-called meta diabetes, depends on destruction of the beta cells. Thus fundamentally the diabetic state in such meta diabetes is pancreatic diabetes—"in effect a removal of the beta cells instead of a removal of the pancreas as a whole." [32]

There is, however, little evidence to support the view that stress imposed by the hypophysis, the adrenal glands or the thyroid accounts for the original development of the clinical entity, diabetes mellitus. The normal healthy pancreas possesses an endurance which appears to be adequate to resist the stresses created by all degrees of endocrine overfunction encountered clinically. Temporary failure occurs in many instances, with resulting hyperglycemia. However, from the fact that the diabetic state so provoked disappears when the hyperfunction of the insulin opponents is corrected, the inference is clear that the overfunction of the pancreatic beta cells has not led to their destruction, and that true diabetes mellitus has not been produced. Exceptions may occur; so far, they have not come to my attention.

Overweight, or the excessive consumption of food which leads to it, imposes a demand for insulin which not only exceeds normal but is of long duration, extending usually over many years. It thus may lead to damage of the beta cells. However, diabetes develops in only a small proportion of persons who are grossly overweight. Therefore, in those cases in which diabetes is provoked by overweight one can logically assume that the pancreas had less endurance than normal from the outset.

Furthermore, in many instances of diabetes, including almost all cases in which diabetes develops in childhood, one finds no grounds for assuming the existence of abnormal stress of any kind. The causation of diabetes in these cases must therefore rest exclu-

sively on a degree of inferiority, anatomic or functional, of the pancreatic beta cells, such that the normal stresses of life imposed by growth, puberty and pregnancy are sufficient to provoke irreversible derangements. Thus, contrary to opinions which have been expressed by Lazarow,[13b] Himsworth,[33] Young,[18b] Bartelheimer[34] and others, one returns to the theory of a unitary origin of diabetes.

Unanswered thus far are those who oppose the theory of a unitary origin of diabetes on the ground that the pancreatic islets in many diabetic persons examined after death show no abnormality. Terbrüggen's[35] recent histologic studies with newer staining methods led him to the conclusion that the pancreatic islets in 80 per cent of cases of human diabetes are small and contain relatively few beta cells but a disproportionate number of alpha cells. Bell,[36] who also used newer staining methods, found an absence or a decided reduction in the number of beta granules in 63 per cent of cases. This leaves 20 to 37 per cent of cases in which there is no anatomic explanation for human diabetes. However, anatomic alterations need not necessarily accompany functional incapacity, and histochemical procedures later may reveal abnormalities not now discernible. In any case, failure consistently to find anatomic abnormality in the pancreas of human beings with diabetes lends no support to the contention that the pituitary body, the adrenal gland or the thyroid play roles of much significance in the basic pathogenesis of human diabetes, for the beta cells in every instance of permanent diabetes produced experimentally by injection of the hormones of these endocrine glands have revealed clear anatomic evidence of damage to the islets.

In any case, the several insulin opponents, endocrine and nervous, including excessive ingestion of food with resulting obesity, important as they are to the regulation of the level of blood sugar, and great as is their influence on the intensity of preexistent diabetes, give rise to diabetes characterized by permanence only when they cause irreversible and in the case of experimental diabetes easily demonstrable lesions of the pancreatic beta cells. This occurs infrequently, if at all, in man, unless the beta cells possess originally and presumably genetically something less than normal endurance. Therefore, in my judgment, diabetes mellitus ought still to be regarded as a clinical entity of pancreatic origin.

Misunderstandings To Be Avoided.—A physician, in his relationship with a patient who is under the care of another physician, should not give hints relative to the nature and treatment of the patient's disorder; nor should a physician do anything to diminish the trust reposed by the patient in his own physician. In embarrassing situations, or whenever there seems to be a possibility of misunderstanding with a colleague, a physician should seek a personal interview with his fellow.

REITER'S SYNDROME: EFFECT OF PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) AND CORTISONE

M. A. OGRYZLO, M D.
and
WALLACE GRAHAM, M D.
Toronto, Canada

In 1916 a case report by Reiter[1] drew attention to a symptom complex of arthritis, urethritis, conjunctivitis and diarrhea. Since this original report many others have appeared in the literature describing a syndrome with variable clinical features and under a variety of titles but most commonly "Reiter's syndrome." In general, emphasis has been placed on the triad of urethritis, conjunctivitis and arthritis; diarrhea has frequently been absent. Although some are of the opinion that one or even two components of the triad may not be present in a particular case, others have reported additional features which occur less frequently. These have included balanitis with superficial circinate lesions on the glans penis, superficial ulcerations on the palate, buccal mucosa or tongue, a keratotic dermatitis of the soles and keratotic or pustular lesions affecting the nails of the toes and fingers. Considerable confusion exists regarding the actual boundary of Reiter's syndrome, and many of the case reports included in the earlier European literature have been rejected by Bauer and Engleman.[2]

All but one of the cases so far reported have occurred in young adult males. Usually the initial symptom is acute nonspecific urethritis, commonly following, but sometimes without, a history of sexual exposure. Diarrhea may accompany or precede the urethritis. Prostatitis and cystitis are not unusual. The conjunctivitis may be mild and unnoticed or may be absent. Generally within a period of two weeks an acute polyarthritis develops, the weight-bearing joints being most commonly affected, often in a symmetric manner. Fever and leukocytosis usually occur, and sometimes generalized lymphadenopathy and splenomegaly. The sedimentation rate is elevated. Skin and mucosal lesions are less common and usually appear only in the more severe cases. The joint changes are not unlike those seen in rheumatoid arthritis except that bony destruction and ankylosis are infrequent. As a rule the disease is self limited over a period of several weeks to months, but recurrences are not uncommon.

The causation of the disease remains unknown, although recent evidence suggests that it may be due to an infection with pleuropneumonia-like organisms. These have been recovered from the genitourinary tract[3]

Canadian Arthritis and Rheumatism Society Fellow in Medicine (Dr. Ogryzlo).

The cortisone acetate was made available by the Department of Veterans' Affairs, Ottawa, Ontario.

From the Medical Service, Sunnybrook (D. V. A) Hospital, Toronto, and the Department of Medicine, University of Toronto

The pituitary adrenocorticotropic hormone used in this study was supplied by the Armour Laboratories, Chicago, Dr. John R Mote, medical director.

Dr A A Fletcher initiated the study of plasma fibrinogen in relation to sedimentation rate The biochemical investigations were carried out, in part, in the laboratories of the Department of Pathological Chemistry, University of Toronto, under the direction of Professors J A Dauphinee and A G. Gornall. These studies will be considered in detail in a later report

and joint fluid,[4] but experimental inoculation has failed to reproduce the disease. A similar symptom complex of arthritis, diarrhea and urethritis or conjunctivitis, or both, has on occasion been observed to occur with dysentery,[5] and it has been suggested that the syndrome may be nothing more than dysenteric polyarthritis with added toxic manifestations.[6] Furthermore, it has been well known that cases of undoubted rheumatoid arthritis may sometimes be complicated by ocular lesions, urethritis or a brief diarrhea.[7]

This report deals not with controversy whether or not Reiter's syndrome constitutes a distinct clinical entity but with the effect of pituitary adrenocorticotropic hormone and cortisone on three patients with a symptom complex which conforms to the syndrome as described by most authors. Two patients received one course of pituitary adrenocorticotropic hormone and the third this drug followed by cortisone, both intramuscularly and orally. The patients received placebo injections both before and after the administration of the drugs and had no knowledge of the changes in medication. Daily observations were made on the clinical response. Laboratory studies included hematological and biochemical changes, erythrocyte sedimentation rates, serum protein fractionations, serum and urinary electrolytes, carbohydrate tolerance, urinary nitrogen excretions, urinary 17-ketosteroids, serial electrocardiograms and electroencephalograms, blood pressure, heart size and changes in body weight.

REPORT OF CASES

Case 1.—G. E. W., a man aged 29, was well until March 1943, when acute arthritis with pain, redness and swelling of the right wrist developed. Three months later the condition spread to the left ankle and both knees. The arthritis gradually subsided over six months, except for residual swelling and restricted movement of the right wrist. There was no history of urethritis or conjunctivitis, but the patient recalled having keratotic lesions on both soles. In subsequent years he had repeated exacerbations affecting one or more of several joints for periods of a few weeks to several months. During one of these episodes in 1945 he had an acute purulent urethritis which lasted for one week, but no neisserian organisms were demonstrated.

On Sept. 17, 1949 he suffered another attack of acute arthritis with severe systemic reaction, anorexia, fever and excessive perspiration. The right ankle and foot, and the left fourth and fifth toes were acutely painful, swollen and red. There was a history of sexual exposure two weeks before this exacerbation, followed in six days by a cloudy urethral discharge in smears of which gonococci were not found. The discharge did not clear, and the arthritis was not prevented by adequate penicillin therapy. With the onset of the joint swelling, painless, shallow, ulcerating lesions developed on the glans penis and in the mouth. There was no conjunctivitis. The man was admitted to Sunnybrook Hospital Sept. 27, 1949.

Examination revealed gross swelling, tenderness, redness and increased heat in the right ankle and foot, the interphalangeal joint of the right great toe and the proximal interphalangeal joints of the left fourth and fifth toes. There was an old deformity of the right wrist with decided restriction of movement. Roentgenograms of the wrist revealed pronounced destructive change with loss of joint space.

Many circinate areas of ulceration were present over the hard and soft palate, with similar lesions on the glans penis and prepuce and with a mild urethral discharge. There was no lymphadenopathy, but the spleen was palpable 3 cm. below the left costal margin. Blood and dark field examinations revealed normal conditions, and urethral smears did not show neisserian organisms.

The urethritis cleared in two weeks, but fever (to 101 F.) persisted for seven weeks. There was some improvement in the pain and swelling in the right ankle and toes, but three weeks after admission there developed an acute exacerbation in the left knee with severe pain, swelling and joint effusion. At the same time scattered hyperkeratotic reddish brown lesions varying from 2 to 5 mm. appeared over both soles. Keratotic lesions with suppuration also involved the nails of the toes and later of the fingers. Some of the toenails were subsequently shed. When the present observations began, the patient was confined to bed or occasionally used a wheelchair.

After placebo injections of saline solution had been given to the patient, pituitary adrenocorticotropic hormone was administered intramuscularly in doses of 25 mg. at six hour intervals throughout the twenty-four hours. Therapy was started Dec. 5, 1949 and was continued for 12 consecutive days.

Joint stiffness disappeared within 24 hours after administration of the drug and joint pain and tenderness after three days. There was a progressive decrease in the joint swelling, although a small amount of free fluid persisted in the left knee and the right ankle and left fourth toe remained a little swollen. The patient became fully ambulatory in three days and regained full range of movement in all joints in one week.

The oral lesions healed in three days and the penile lesions in 12 days. There was progressive healing of the keratodermia of the feet and about the nails, with considerable desquamation of the overlying skin. The sedimentation rate (Westergren), dropped from levels of 70 to 90 mm. per hour to 7 mm. per hour after 11 days. A distinct change in the mental attitude of the patient was manifested by mental exhilaration and mild euphoria.

Two days after withdrawal of the drug there was a mild recurrence of swelling and pain in the affected joints and reappearance of the lesions in the mouth, genitalia and soles. These were not severe and subsided gradually over the next four weeks. The sedimentation rate increased to 37 mm. in one hour but subsequently dropped to normal levels as the patient improved. He was discharged from the hospital on Feb. 6, 1950 and is now fully employed.

Case 2.—F. W., a married man aged 35, had an injury to his left knee in 1944 followed by stiffness, swelling and intermittent locking. In June 1944 the medial meniscus was removed, after which there was a rather slow recovery with residual stiffness persisting. On Oct. 1, 1949 there rapidly developed stiffness, pain and swelling of the right knee and local redness. One week later there occurred mild urethritis and soreness of the gums. Scattered, small, brownish lesions appeared on the soles. There were no eye symptoms.

The patient was admitted to Sunnybrook Hospital Oct. 16, 1949 with a temperature of 100 F. Over the posterior part of the palate and left buccal mucosa were small reddened areas of superficial ulceration, which extended to the inner gingival margin. The tongue was acutely inflamed. There was no lymphadenopathy or splenomegaly. The glans penis was reddened and excoriated with several areas of superficial ulceration, and there was a mild urethral discharge. The right knee was hot, red, swollen and acutely painful, with restriction of flexion and extension. The left knee was moderately swollen and tender with a small effusion but had a full range of movement. Over the soles there were a number of small, firm, brownish hyperkeratotic lesions. Smears and cultures of the urethral discharge were negative for gonococci or pleuropneumonia-like organisms. The sedimentation rate (Westergren) varied between 67 and 86 mm. per hour.

During his first two months in the hospital the patient showed some improvement, with clearing of the urethral discharge and gradual healing of the lesions on the soles. Some swelling and effusion persisted in the knees, although he was partially ambulatory. The oral and genital lesions improved but did not entirely heal. The sedimentation rate dropped to 15 mm. per hour. Pituitary adrenocorticotropic hormone was administered in doses of 10 mg. four times daily, commencing Jan. 23, 1950, for 14 consecutive days. It was preceded and followed by placebo injections. Within 48 hours there was a progressive decrease in joint pain and stiffness; a full range of movement was possible at the end of 10 days. Joint swelling and effusion gradually subsided in three days, but slight residual thickening persisted. The patient became fully ambulatory by the fifth day. The lesions in the mouth and on the glans penis healed in seven days. The sedimentation rate dropped to 1 mm. per hour. Although his mental outlook improved significantly he became emotionally more labile, experiencing periods of elation and on one occasion displaying unusual depression with weeping.

Within 24 hours of the discontinuance of the drug, pain and stiffness recurred in the right knee and fluid reappeared in the joint. Acute glossitis developed after 24 hours, progressing to superficial erosions along the margins of the tongue, while similar erosions occurred on the roof of the mouth. The genital lesions did not recur. Two weeks later the mucosal lesions were again healed, and all joint swelling subsided in four weeks. The patient was discharged from the hospital on April 26, 1950 without disability and is now employed.

CASE 3.—D. A. F., a married man aged 24 years, was admitted to the hospital in 1946 with pain, swelling and effusion of about 12 months' duration in the left knee. He denied any history of venereal disease. The swelling subsided promptly over a period of six weeks, but shortly afterward recurred in both knees. He received a course of gold sodium thiomalate (myochrysine®) totaling 1.675 Gm. and a course of fever induced by typhoid vaccine, but he had frequent exacerbations in one or both knees over a period of 30 months. The arthritis finally subsided, and he remained well for one year before his present admission.

On March 26, 1950 he noticed a cloudy urethral discharge, and when he awakened the next morning both knees were red, swollen and acutely painful. Two days later a diffuse vesicular eruption appeared over the glans penis with rupture of some of the vesicles, leaving small superficial erosions. On the fifth day both ankles were involved. The illness was associated with fever, excessive sweating, anorexia and on one occasion nausea and vomiting. There was no diarrhea. He was admitted to Sunnybrook Hospital on April 3, 1950.

On admission the patient was acutely ill and perspiring profusely. His temperature was 101 F. There was injection of the conjunctival vessels but no purulent discharge. A small herpetic lesion was on the upper lip. Lymphadenopathy was not present, and the spleen was not palpable. A diffuse vesicular eruption covered the glans penis, extending back beyond the corona, and there was a purulent urethral discharge. Both knees were hot, red, swollen and acutely tender. Movement produced excruciating pain. Both ankles were tender with slight swelling in the right ankle. Urethral smears were negative for neisserian organisms. The reaction of the blood to the Kahn test was negative, and the sedimentation rate (Westergren) was 110 mm. per hour.

His condition remained relatively unchanged during the first 12 hospital days, except for clearing of the urethral discharge. Treatment with pituitary adrenocorticotropic hormone was begun April 13, 1950 in doses of 25 mg. every six hours for 14 days.

The joints remained acutely painful for the first four days, after which there was a gradual but progressive decrease in the pain, swelling and tenderness, and a noticeable clearing of the genital lesions. He was ambulatory after 10 days with little pain in the knees, although he could not extend them fully. There was slight periarticular swelling, some tenderness and a little fluid in each knee at the end of 14 days. The penile lesions healed completely, and the sedimentation rate dropped to 39 mm.

Within 14 hours of discontinuance of the drug the patient had a severe relapse with acute pain, swelling and increased heat in all the joints previously affected plus pain and swelling in the left wrist and left shoulder. Several ulcers appeared on the tongue, and the urethral discharge recurred, with a return of the vesicular lesions on the glans penis. The sedimentation rate increased to 93 mm. in seven days. On the third day after therapy ended he had several episodes of oppressive pain in the retrosternal area, lasting up to 30 minutes without radiation and unaffected by breathing.

Eight days after discontinuance of the drug the patient was started on cortisone acetate administered intramuscularly in two daily injections. He received 300 mg. daily for 3 days, 200 mg. daily for 10 days and 150 mg. daily for 10 days, totaling 4.4 Gm. Slight improvement was evident within 24 hours, becoming more definite after 48 hours with decrease in joint pain and swelling, increase in range of movement and clearing of the urethral discharge and genital lesions. By the sixth day he had little joint pain; by the eighth day he was ambulatory. Improvement was gradual thereafter, but although he was able to walk comfortably he continued to have slight tenderness in all the affected joints, with some residual swelling and a little fluid in each knee joint. Flexion and extension of the knees remained slightly limited. The sedimentation rate dropped to 31 mm. by the sixteenth day.

Relapse of joint symptoms after the withdrawal of cortisone intramuscularly given was more gradual than that after pituitary adrenocorticotropic therapy. There was slight increase in pain, tenderness and swelling in all the affected joints within 48 hours. A small number of vesicles again appeared on the penis after 72 hours. Within seven days there was a full relapse of the arthritis with increased pain and swelling in the knees, the ankles and the left wrist, though somewhat less severe than that following the initial course of hormonal therapy. The sedimentation rate increased progressively to a maximum of 108 mm. after 12 days. Although some improvement occurred during the next five weeks, the patient continued to have pain with swelling in the affected joints and the erythrocyte sedimentation rate remained high.

After Freyberg[8] and Hench[9] reported the effectiveness of cortisone orally in tablet form this patient was given a second course of cortisone acetate by the oral route, using the injectable material as supplied in ampul form. The drug was given in two divided doses, 12 hours apart, commencing July 4, 1950. He received 300 mg. orally each day for three days, 200 mg. daily for 10 days and 150 mg. daily for 4 days, a total of 3.5 Gm.

On this occasion there was a noticeable reduction in joint pain and stiffness within six hours and nearly complete relief of pain and local tenderness in 24 hours. Range of movement at the knees returned almost to normal, and he again became ambulatory. During this remission, as in the others, slight swelling with a small amount of fluid persisted in the knees, although pain was for the most part abolished. The sedimentation rate dropped progressively to 23 mm. per hour by the seventeenth day.

It appeared that the remission induced by the orally administered cortisone was in every way comparable to that following pituitary adrenocorticotropic or cortisone therapy by intramuscular injection. Subjective relief of joint pain and stiffness actually occurred more quickly. Withdrawal of the hormone was again followed by an increase in the sedimentation rate and a return of joint pain over a period of five to seven days. This time, however, the relapse was of a rather mild character and did not confine the patient to bed. He is still under observation, although he is considerably improved.

CLINICAL OBSERVATIONS

The foregoing case reports clearly demonstrate that patients with so-called Reiter's syndrome respond dramatically to the administration of either pituitary adrenocorticotropic hormone or cortisone. The improvement in these patients was prompt and sustained during the period of drug administration. Joint swelling subsided rapidly and pain and tenderness disappeared, although some evidence of residual arthritis persisted in a mild form. Relapse on withdrawal of the hormones was rather prompt in all cases, but the symptoms usually were not as severe and the subsequent course was one of improvement. The skin and mucosal lesions followed a similar pattern.

[8] Freyberg, R. H.: Data read before the American Rheumatism Association, San Francisco, June 23, 1950.

[9] Hench, P. S.: Data read before the American Rheumatism Association, San Francisco, June 23, 1950.

No appreciable difference could be detected in the clinical response to the two drugs in the third patient, except that the relapse after the intramuscular injection of cortisone was more gradual and less severe, but this was probably due to his initial improvement after the use of pituitary adrenocorticotropic hormone.

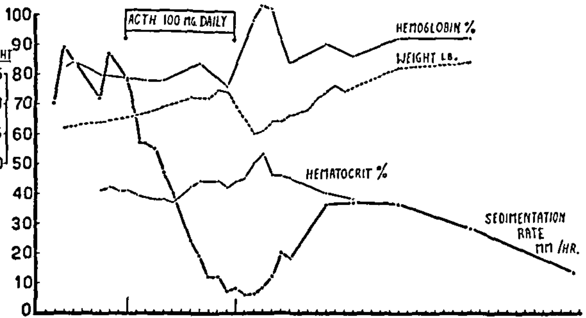

Fig. 1 (case 1). — Effect of pituitary adrenocorticotropic hormone (ACTH) on hemoglobin, hematocrit, sedimentation rate and body weight.

When cortisone was given in comparable doses in this patient, it was equally effective in inducing a remission of symptoms whether it was administered by the intramuscular or the oral route. The response was prompter following its oral administration and appeared to be equally well sustained. This observation has also been confirmed in patients with rheumatoid arthritis,[10] although there is some indication that the required dose may be a little larger than with intramuscular injections. Recurrence of joint pain after orally administered cortisone was much less severe than after the intramuscular injections, possibly due to the over-all benefit derived from the previous two courses of hormone administration.

The fact that in two patients a single course of pituitary adrenocorticotropic therapy was able to produce a prompt remission of the disease, followed by a mild short-lived relapse which went on to gradual recovery, is significant from the point of view of a practical therapeutic measure. It was believed that the course of the illness was materially shortened in both instances and probably also in the third. In rheumatoid arthritis such lasting benefit has been observed only in an occasional patient,[11] and the more hopeful result in Reiter's syndrome is no doubt due to the self limited nature of this disease.

Only one of the three patients (case 3) was febrile when the present observations were begun. The oral temperature dropped from levels of 101 to 102 F. to normal within 24 hours of institution of pituitary adrenocorticotropic therapy but rose promptly the day after the drug was withdrawn. It again dropped to normal within three days of his receiving cortisone, but on withdrawal it again became elevated, though not to its previous level.

Decided stimulation of appetite with gain in weight was evident in all three patients. Some of the weight gain was obviously due to water retention and was promptly lost when hormonal therapy was discontinued, but part of the gain was nutritional and was maintained. Improvement in mental outlook was prominent in all three patients, and a mild euphoria was noticeable in one. One patient was exceedingly labile and exhibited a transient mild depression with weeping on one occasion.

Serious complications were not observed. Transient pain at the site of injection was common. Two patients had a mild acneform eruption on the face and shoulders. Ringing in the ears occurred in one patient but was not troublesome. Two patients complained of moderately severe, constricting pain across the anterior part of the chest or retrosternally, beginning within two or three days after discontinuance of pituitary adrenocorticotropic hormone. This occurred in episodes lasting up to half an hour but was not associated with sweating or signs of shock. Examination of the heart revealed no evidence of cardiac impairment, and the symptoms subsided within two days. In one patient the retrosternal pain was accompanied with recurring abdominal cramps without diarrhea. No significant change in blood pressure or heart size was noted.

LABORATORY OBSERVATIONS

A decrease in the total circulating eosinophils was observed during administration of both hormones. Cortisone was effective (case 3) in lowering the eosinophil count whether given by the intramuscular or the oral route, but toward the end of the period of intramuscular administration the total count increased gradually to its previous level, although symptoms were well controlled.

The total white blood cell count increased in two patients while they were receiving one of the two drugs. One patient showed no rise in leukocyte count. The counts increased to as much as 24,200 per cubic millimeter, due entirely to a polymorphonuclear leukocytosis. There was little alteration in the absolute number of lymphocytes.

The hemoglobin concentration and red blood cell counts decreased slightly during the period of hormonal administration. This was interpreted as being due to hemodilution, since it coincided with evidence of water retention. On the discontinuance of treatment with either of the agents there was a rise in both the hemoglobin and red cell counts coinciding with the period of water diuresis and weight loss. The rise was interpreted as being largely due to hemoconcentration because the count subsequently dropped, but the rise was also due

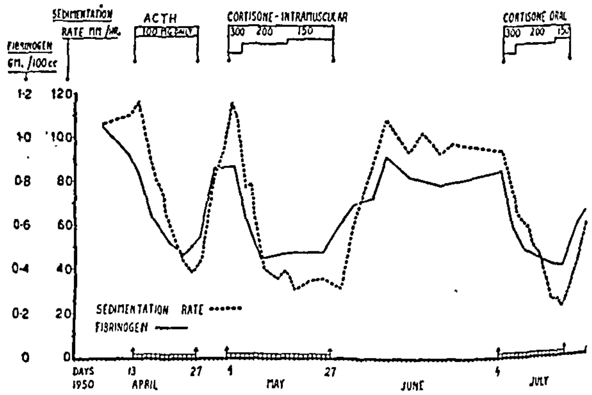

Fig. 2 (case 3). — Effect of pituitary adrenocorticotropic hormone (ACTH) and cortisone on sedimentation rate and plasma fibrinogen.

---

[10] Ogryzlo, M. A.: Unpublished data.

[11] Hench, P. S., and others: Effects of Cortisone Acetate and Pituitary ACTH on Rheumatoid Arthritis, Rheumatic Fever and Certain Other Conditions, Arch. Int. Med. 85:545 (April) 1950.

in part to an absolute increase since in two patients it was subsequently maintained at a higher level.

Sedimentation rates dropped rapidly to normal or near normal levels during both forms of therapy but increased again on withdrawal. The decrease in sedimentation rate was as prompt with orally administered cortisone as with the intramuscularly given drug. With the more lasting clinical improvement after the discontinuance of pituitary adrenocorticotropic therapy the sedimentation rate again dropped in a corresponding fashion in the two patients whose studies are complete (fig. 1).

Estimation of the urinary electrolytes in one patient (case 1) maintained on a fixed intake of sodium and potassium showed decided sodium and chloride retention during the first three days of his receiving pituitary adrenocorticotropic hormone and an immediate pronounced diuresis on withdrawal. The potassium excretion showed little change. Serum sodium and chloride levels were raised, while the serum potassium was lowered by the administration of the drug.

Two patients (cases 2 and 3) who were maintained on a constant dietary intake showed a decided increase in the daily excretion of total nitrogen, urea nitrogen and amino acid nitrogen in the urine, while they were receiving pituitary adrenocorticotropic hormone; these values fell sharply on withdrawal of the drug. The increase was sufficient to induce a negative nitrogen balance. Uric acid excretion was only moderately increased, and the serum uric acid was lowered slightly.

The serum protein fractions were normal in all three patients. A significant drop in the total globulin occurred in each instance, largely because of a drop in the euglobulin fraction. The plasma fibrinogen was abnormally high in two patients (cases 1 and 3) and was observed to drop dramatically to normal levels while they were receiving either of the two drugs. The third patient (case 2) also showed a drop in plasma fibrinogen, even though it remained within the normal range. On withdrawal of either of the two hormones the plasma fibrinogen levels again rose to approximately their former levels. In patients with rheumatoid arthritis the level of plasma fibrinogen has been observed to parallel closely the clinical activity of the disease process and to bear a close relation to the erythrocyte sedimentation rate.[12] The same parallelism of clinical activity, sedimentation rate and plasma fibrinogen was observed in these patients (fig. 2).

A definite decrease in tolerance to orally administered glucose was demonstrated in two patients, with an elevation of tolerance curve, during the period of pituitary adrenocorticotropic therapy. Glycosuria was not noted. A significant increase in the daily excretion of the urinary 17-ketosteroids occurred in all three patients while they were receiving the hormone. No change was observed in the basal metabolic rate in one patient. Electrocardiographic changes were confined to slight lowering of the height of the T waves during the period of administration of either of the hormones. This was probably due to a lowering of the serum potassium. Electroencephalographic changes were minimal. In two patients low voltage, slow wave activity, three to six per second, appeared during the period of pituitary adrenocorticotropic hormone administration, with a return to the previous alpha rhythm on withdrawal.

SUMMARY

Pituitary adrenocorticotropic hormone (ACTH) was administered to three patients with the clinical symptoms of Reiter's syndrome. One of these subsequently received cortisone both intramuscularly and orally. The response in each instance was prompt and dramatic. Withdrawal of the hormones was followed by a relapse of symptoms, mild in two patients and more severe in one. Two of the patients have recovered after the initial relapse and are now fully employed, but the third is still under observation. The course of the disease was materially shortened in the two patients who have recovered and probably in the third. The sustained improvement in two patients suggests a possible therapeutic application of pituitary adrenocorticotropic hormone and cortisone in a self limited disease such as Reiter's syndrome. Cortisone was effective in inducing a remission of symptoms whether administered by the intramuscular or oral route.

HYPERTHYROIDISM, PREGNANCY AND THIOURACIL DRUGS

GEORGE O. BELL, M.D.
Boston

The literature on the use of thiouracil drugs in the treatment of hyperthyroidism complicated by pregnancy is scant and in most instances is confined to reports of one or two cases. My experiences and those of associates at the Lahey Clinic with 21 such cases are, therefore, being reported with the hope of partly filling in this gap in our knowledge.

Since the introduction of thiouracil in 1943, this drug or its derivatives have been used at the clinic in the preoperative preparation of over 1,900 thyrotoxic patients. There were 21 women whose hyperthyroidism was complicated by pregnancy. Three patients had recurrent hyperthyroidism, and 18 had primary hyperthyroidism. Subtotal thyroidectomy was performed on each patient during the course of the pregnancy after she had been prepared with one of the thiouracil drugs and strong iodine (Lugol's) solution. The duration of hyperthyroidism ranged from two months to four years. The duration of pregnancy at the time of operation ranged from three weeks to five months. The average basal metabolic rate before antithyroid treatment was + 48 per cent and before operation + 10 per cent. The amount of thyroid tissue removed at operation averaged 70 Gm. Antithyroid drugs were administered for periods ranging from 28 to 90 days; all 21 mothers underwent thyroid surgery without complications and recovered fully. The pregnancy did not influence the course of the hyperthyroidism or its response to thiouracil drugs.

Follow-up reports from the patients on the pregnancies are incomplete. Since the clinic does not have an obstetrics department, all patients who had undergone thyroid operation were referred to their own obstetricians for further care. No special thyroid or iodine treatment was prescribed. Six women have not yet reached full term and are apparently well. Ten women were delivered at term of 11 normal children. One woman aborted at five months, and two women were delivered prematurely at eight months; one of a

---

From the Department of Internal Medicine, Lahey Clinic.

macerated stillborn fetus and the other of a "deformed"[1] baby who died four hours after birth. Preeclampsia developed in one patient near term, and the child died at birth. One woman was delivered by cesarean section at term, and the baby died six hours later. The fetal loss in the 15 patients whose pregnancies have terminated is 33 per cent.

Reports on 11 living children indicate that all were normal at birth and have developed normally since then. Their present ages range from 11 months to 5 years. One set of twins is now 5 years old; both children are well in all respects.

COMMENT

The association of hyperthyroidism and pregnancy is uncommon. The incidence of hyperthyroidism among pregnant women is about 0.2 per cent, whereas the incidence of pregnancy in patients with hyperthyroidism ranges from 0.41 to 3.0 per cent.[2]

The number of cases herein reported is too small to permit final conclusions. The outstanding fact, however, is the unsuccessful outcome of five pregnancies. Such a result may well have been inevitable and totally unrelated to the thyroid disease, the antithyroid medication or the thyroid operation. Nevertheless, inspection of such a relation is worthy of consideration.

The problems presented by this combination of conditions may be considered under three main divisions: (1) the mother and the hyperthyroidism, (2) the pregnancy and its complications and (3) the child.

THE MOTHER

With the use of the thiouracil drugs, it is now possible to control hyperthyroidism completely, no matter how severe it may be. Full control of hyperthyroidism permits the surgeon to perform subtotal thyroidectomy with little risk to the patient and with an excellent chance of obtaining a complete remission of the disease. At the clinic, we have felt that the patient who has the combination of hyperthyroidism and early pregnancy should have the hyperthyroidism eliminated by subtotal thyroidectomy after preparation with one of the thiouracil drugs and strong iodine solution. Reports in the literature provide ample evidence that subtotal thyroidectomy during the course of pregnancy does not disturb the pregnancy. Abortions immediately following thyroid operations are unusual, and the postoperative complications of tetany or myxedema are rare. Our pregnant patients have had subtotal thyroidectomy performed through the fifth month of pregnancy, and the operation is probably safe through the first six months. Hyperthyroidism during the last trimester is probably best treated by antithyroid drugs until sometime after delivery when subtotal thyroidectomy can be done.

THE PREGNANCY

Uncontrolled hyperthyroidism is accompanied by a high incidence of abortions, premature births and toxemias. Javert[3] reported an incidence of toxemia of pregnancy associated with hyperthyroidism of 77 per cent, Kibel[4] 55 per cent and McLaughlin and McGoogan[5] 26 per cent. Brandes[6] at the Mayo Clinic found no increase in toxemias of pregnancy among 75 patients with hyperthyroidism. This wide discrepancy in reports is difficult to explain, but the weight of evidence favors the fact that toxemias may occur oftener when hyperthyroidism complicates the pregnancy. Relief of the hyperthyroidism as quickly as possible would eliminate whatever influence this factor may have on the incidence of such complications.

Hypothyroidism, on the other hand, has also been thought to be an important factor in the cause of toxemias of pregnancy. Hughes[7] found that the administration of desiccated thyroid to all normal pregnant women with basal metaboilc rates below zero reduced the incidence of preeclampsia by 50 per cent as compared with an equally large control group to whom no thyroid was given. Patterson, Nicodemus and Hunt[8] claimed that a relative state of hypothyroidism leads to changes in the placenta which produce late toxemias of pregnancy and that the administration of desiccated thyroid early in pregnancy would prevent these.

Peters, Man and Heinemann[9] found that the serum-precipitable iodine is high throughout normal pregnancy, falling shortly before delivery. Their data suggest that, if the serum-precipitable iodine is low early in pregnancy, miscarriage is likely to occur. Administration of thyroid to such patients resulted in a rise in the level of serum-precipitable iodine and permitted the patients to go to term.

Delfs and Jones,[10] in a study of abortion, found that low chorionic gonadotropins were often associated with abortions and that low thyroid function was found to occur frequently with low chorionic gonadotropins. Decreased thyroid function may possibly be a major factor in the cause of recurrent abortions.

Hypothyroidism induced in female adult rats by prolonged administration of thiouracil drugs does not cause sterility but does interfere with the continuation of gestation, causing resorption of fetuses in 100 per cent of cases. If the drug is given for less than 100 days some rats do deliver normal litters. It was concluded that resorption of fetuses was the result of the induced myxedema and not of the thiouracil toxicity.[11]

The management of hyperthyroidism in pregnancy with thiouracil drugs either preoperatively or as prolonged treatment must, therefore, take into account the possible harm to the pregnancy from the inadvertent production of myxedema. Furthermore, the temporary depression of the metabolism which often occurs during the first three or four months following thyroidectomy should be viewed with equal concern.

THE CHILD

The possible effect of thiouracil on the fetus has been the center of attention of recent writers. In 19 reports[12] on the outcome of pregnancy in women who have received the thiouracil drugs, there were 22 normal children. Two fetuses were examined at five months, when the pregnancy was interrupted, and both were found to have hyperplastic and enlarged thyroids. One full term infant had an enlarged thyroid, which eventually returned to normal size. One child was born prematurely but was otherwise normal. One child was an anencephalic monster whose thyroid was found to be normal, and exophthalmos developed in one child, normal at birth, at 2 months of age with subsidence at 3 months of age.

Experimental use of thiouracil drugs in pregnant rats has resulted in activation and hyperplasia of the thyroid and retarded growth in the offspring, changes which are temporary if treatment with the drug is stopped.[13]

Freiesleben and Kjerulf-Jensen[14] in experiments on *rats proved that thiouracil compounds are transmitted* from mother to fetus through both the placenta and the breast milk. Furthermore, thyroid hyperplasia in infantile rats could be prevented by concurrent administration to the mothers of thyroid hormone along with the thiouracil drug. They concluded that the danger to infants is not from the thiouracil itself but from the low concentration of thyroxin in the tissues, induced by the thiouracil.

In 1921 Marine and Kimball[15] noted that Halsted had shown in dogs that if the thyroid is removed before or at an early stage of pregnancy and rigid precautions are taken to exclude iodine the young at birth have enlarged thyroids, whereas if iodine is available the young at birth will have normal thyroids. In addition, these same authors reported that there is always a decrease in the iodine content of the mother's thyroid during pregnancy and that the administration of iodine to all pregnant women (particularly in the goiter belt) lessened drastically the incidence of congenital goiter, cretinism and other evidences of thyroid dysfunction.

Parkin and Greene,[16] reporting on pregnancy occurring in cretinism and myxedema, cited the histories of six women who came under their observation. One was pregnant at the time of writing. The other five had had a total of 10 pregnancies, six ending in delivery of full term normal infants and three terminating in abortions—a fetal loss of 30 per cent.

Reports on hyperthyroidism and pregnancy in which the outcome of the pregnancies is recorded indicate a fairly high percentage of fetal loss. Gardiner-Hill[17] found that 54.5 per cent of such pregnancies terminated unsuccessfully. Clute and Daniels[18] reported 15 pregnancies in which subtotal thyroidectomy was done during the pregnancy with the excellent results of 14 normal living babies and one miscarriage. Mussey, Plummer and Boothby[19] in 1926 reported 42 pregnancies with adequate follow-up of 37; the fetal loss was seven, or 19 per cent. Mussey, Haines and Ward[12e] (1948) reported an additional 30 pregnancies associated with hyperthyroidism in which the follow-up of 20 was adequate. The fetal loss was four out of 20, or 20 per cent.

CONCLUSIONS

Several factors appear to influence the pregnancy which is complicated by hyperthyroidism, namely, the hyperthyroidism, thiouracil drugs, iodine lack and thyroid hormone lack. The hyperthyroidism can be quickly terminated with little risk to the mother by the use of antithyroid drug preparation and subtotal thyroidectomy. *Furthermore, after such treatment, the babies* which are born alive at full term, although rarely showing transient enlargement of the thyroid, are usually normal and develop normally thereafter. Attention must be focused chiefly on the difficulties arising in the *pregnancy and the fetus.* Uncontrolled hyperthyroidism is attended by a high incidence of fetal loss and late complications of pregnancy, but with current antithyroid therapy uncontrolled hyperthyroidism should cease to be a problem. Myxedema or decreased thyroid function is detrimental to the outcome of the pregnancy as well as to the offspring. It is likely that this factor may be most important in the progress of the pregnancy and measures to combat it may possibly prove to be most valuable. The use of desiccated thyroid or iodine in pregnancy is not a new idea, but its use in connection with pregnant patients who have been treated with thiouracil drugs and subtotal thyroidectomy for hyperthyroidism has not been emphasized or urged. Whether the results of pregnancy can be improved remains to be seen, but it seems desirable to apply the following suggestions:

1. Induced myxedema should be avoided in patients receiving a thiouracil drug by repeated observations of the metabolic rate and blood cholesterol throughout the period of medication. It is to be remembered that the basal metabolic rate in normal pregnant women remains at a normal level until the sixth month. Thereafter it rises to a level of + 20 or + 25 per cent during the last trimester.

2. Lowered metabolic levels after thyroidectomy should be avoided by the administration of desiccated thyroid throughout the remainder of the pregnancy. One to 2 grains (60 to 120 mg.) of desiccated thyroid daily should provide enough thyroid hormone and probably enough iodine to eliminate any existing iodine and thyroid hormone lack, and 3 to 5 drops of strong iodine solution daily would certainly provide sufficient iodine.

3. The above measures may prove to be sufficient in those women whose histories reveal other normal pregnancies. In those women with histories of previous unsuccessful pregnancies the diethylstilbestrol therapy

of Smith and Smith[20] should be added to the aforementioned measures. These authors have obtained excellent results in the prevention of late complications of pregnancy and associated fetal loss. Its use in our type of patient, by helping to maintain normal growth and development of the placenta, may possibly improve our current statistics of 33 per cent fetal loss.

4. Closer cooperation between obstetricians and thyroidologists is urged. Careful follow-up of the results of pregnancy in women with hyperthyroidism may throw further light on this aspect of the problem, and the actual need for such treatment as suggested herein may be more clearly defined.

SUMMARY

Study of 21 women whose hyperthyroidism complicated their pregnancy revealed the following facts:

1. Subtotal thyroidectomy after preparation with thiouracil drugs and iodine can be done safely during the first two trimesters with little risk to the patient and with remission of the hyperthyroidism.
2. Full term living infants born to such patients have been normal.
3. Results of pregnancy in 15 women who have been followed to term include 10 full term normal deliveries with 11 healthy children, one abortion at five months, two premature births at eight months (one a macerated fetus and one deformed infant that died four hours after birth), one case of toxemia at term with death of the infant and one cesarean section at term with death of the infant six hours later. This represents a fetal loss of 33 per cent.
4. A higher fetal salvage is desirable, and arguments are presented which show the dangers particularly of hypothyroidism which either is induced by antithyroid drugs or occurs subsequent to thyroidectomy.
5. Therapy directed toward fetal salvage is suggested and includes the avoidance of overdosage with antithyroid drugs, the administration of thyroid and iodine after thyroidectomy and the possible use of diethylstilbestrol therapy throughout pregnancy.

Rabies in Animals.—In the United States, epizootics in skunks have been responsible for at least fifty cases of human rabies. A nickname for skunks in the West is "phobey" cat because of the animal's role in causing hydrophobia. In Kansas, in 1873, about forty people, primarily men who camped out on the plains, died of rabies caused by skunk bites. In Arizona, in 1907, rabid skunks were said to have caused the death of 10 people. California, Oregon and Nevada had a huge outbreak of rabies in wild animals in 1915 and 1916. The coyote was the principal vector in this case. To illustrate how a vigorous campaign of wildlife decimation will stop an epidemic of rabies and eventually eradicate it, Nevada's experience is worth citing. By 1931, that State had rid itself of rabies, but only after 89,000 coyotes, bobcats and mountain lions were destroyed as well as several thousand smaller mammals. Fox rabies has been on the increase in the United States since 1940. Especially involved have been the Southeastern States. However, New York State has a remarkable feature; dog rabies has been controlled effectively while fox rabies is still rampant. In those areas where wildlife rabies exists, there is also a correspondingly great loss from cattle rabies. New York State is such an example.—Raymond Fagan, Rabies in Animals Other Than Dogs, *CDC Bulletin*, U. S. Public Health Service Communicable Disease Center, Atlanta, Ga., October 1950.

RELATION OF CREATININE TO NONPROTEIN NITROGEN IN AZOTEMIC STATES

Extrarenal azotemia, it seems to us, is a nonspecific term that has been used to describe such varied conditions as acute renal insufficiency, reversible uremia, lower nephron nephrosis, shock kidney and crush syndrome. The use of these terms almost interchangeably in the literature has resulted in considerable confusion. It is probable that many of the conditions classified under these headings are of different pathogenesis and that the pathological picture in the kidney will vary. Also, the pathogenesis may be of extreme diversity, varying from peripheral vascular collapse in acute toxemias to late secondary shock in traumatic injuries and including medical, surgical, obstetric, dermatological and orthopedic conditions. Because of such diversity, it seems improbable that the renal effect is always identical.

It has been our observation that there were occasional cases in which a disproportion in the relation between creatinine and nonprotein nitrogen existed. It was our general impression that this disproportion was observed more commonly in conditions of extrarenal azotemia. A survey of the English literature has revealed a paucity of information on the significance of the relation between the rise in nonprotein nitrogen values and the rise in creatinine values, especially in conditions other than primary renal insufficiency. Bell and Knutson[1] stated that in extrarenal azotemia there is no constant relation of these two components. Fishberg[2] has observed that the increase in urea content of the blood may be considerable before the creatinine value rises in acute glomerulonephritis and in prerenal azotemia. Patch and Rabinowitch,[3] in a statistical analysis of a large series of observations, reported that when the creatinine values were normal or nearly normal, symptoms of uremia were usually absent in spite of the high urea values. Livermore[4] stated that, while urological obstructive cases early may show a normal or low creatinine content with a high nonprotein nitrogen level, in long-standing obstruction the creatinine and nonprotein nitrogen values are both high. Although numerous detailed studies of the syndrome of extrarenal azotemia appear in the literature,[5] there are curiously few reports on creatinine levels. Therefore, it appeared worth while to investigate this relation in cases of extrarenal azotemia, primary renal azotemia and postrenal or obstructive uropathies.

MATERIAL AND METHODS

The patients studied in this investigation were mainly from the Cook County and the Mount Sinai hospitals. The classification of our cases into the three categories was determined by clinical and laboratory findings, and, in many cases, by postmortem examinations. Of the 22 patients with extrarenal azotemia, there were 12 deaths and eight autopsies. Repeated determinations of nonprotein nitrogen by the method of Koch and McMeekin,[6] creatinine by the method of Folin and Wu[7] and urea nitrogen as described by Gentzkow[8] were done on these patients. Urine examinations consisted of determinations of albumin, sugar, acetone and specific gravity and microscopic examination of the sediment. When practicable, total urinary output was measured. The study consists of 22 cases of extrarenal azotemia, 15 of primary renal azotemia and seven cases of postrenal azotemia. All chemical determinations were done in the same research laboratory at the Chicago Medical School by the same technician.

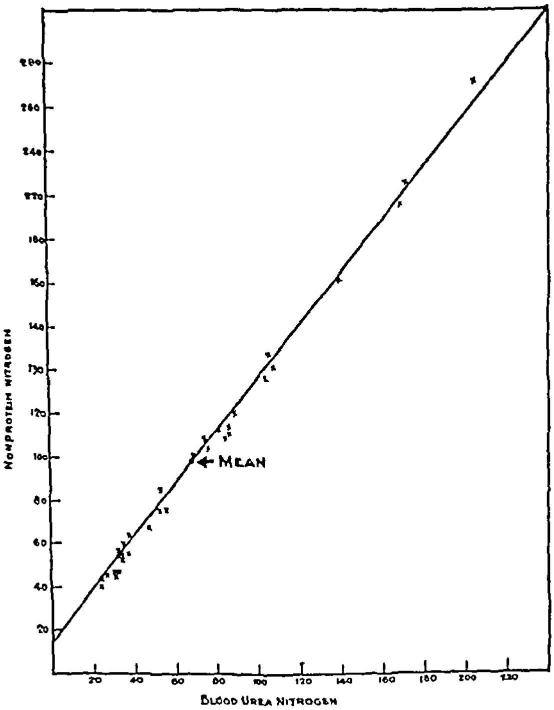

Fig 1—Values in all figures are given in milligrams per 100 cc

There was a wide variety of causative conditions in the cases of extrarenal azotemia, such as pneumonia, heart failure, hepatic diseases, diabetic acidosis, acute pancreatitis, crush syndrome, hyponatremic acidosis, hypochloremic alkalosis and sulfonamide reactions. The causative conditions in the cases of primary renal azotemia were of all the usual types other than acute glomerulonephritis. The postrenal azotemia group consisted of patients with benign prostatic hypertrophy and patients with obstructive cancer of the lower urinary tract. Patients were selected at random in these three categories. The primary object of this report was a study of nonprotein nitrogen partitions in extrarenal azotemia. The other two categories were studied for comparative and control purposes. The treatment of these patients was not under our management. During the period of study, treatment of extrarenal azotemia varied considerably, and, therefore, no consistent form of therapy was followed.

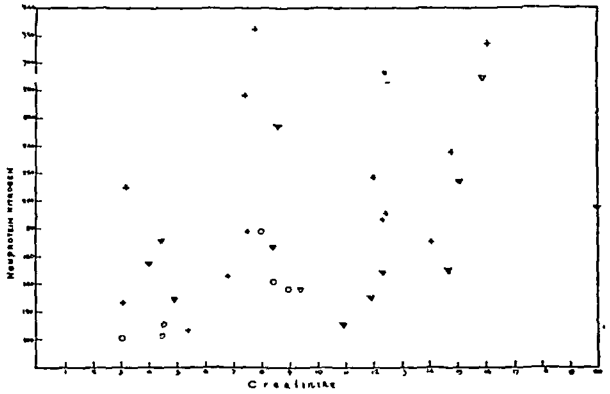

Fig 2—Relation of creatinine to nonprotein nitrogen in three types of renal insufficiency The inverted triangle represents renal insufficiency; the plus sign represents extrarenal insufficiency and the circle postrenal insufficiency

RESULTS

In the analysis of the nonprotein nitrogen, blood urea nitrogen and creatinine values in 33 serums from 26 patients of all three categories, a linear correlation was found between nonprotein nitrogen and blood urea nitrogen of 0.996 plus or minus 0.001. In 56 serums from 44 patients a correlation coefficient of nonprotein nitrogen to creatinine of 0.892 plus or minus 0.018 was found.

Our data indicate that the nonprotein nitrogen and urea values can be computed from each other by the use of the regression formulas:

$$\text{urea} = 0.82\,(\text{N.P.N.} - 10.3)$$
$$\text{N.P.N.} = 1.21\,(\text{urea} + 12.4).$$

The straight line in figure 1 is drawn from an average of the two regression formulas.

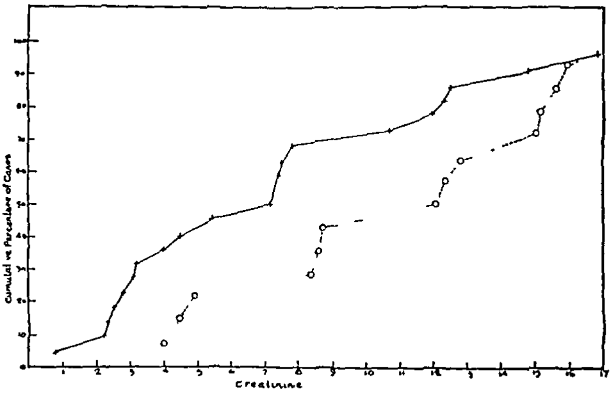

Fig. 3—Cumulative distribution polygons for creatinine levels in extrarenal and renal azotemia based on values associated with the single or maximum nonprotein nitrogen determination for each case The unbroken line represents 22 cases of extrarenal azotemia and the broken line 14 cases of renal azotemia

Our results substantiate the work of previous authors,[9] in that, at lower levels of azotemia, urea constitutes about 50 per cent of the nonprotein nitrogen, and at progressive increments of nonprotein nitrogen it rises to constitute almost 90 per cent.

[9] Peters, J. P, and Van Slyke, D D: Quantitative Clinical Interpretation, ed 2, Baltimore, Williams & Wilkins Company, 1946, vol 1.

Of the 13 patients with primary renal azotemia with nonprotein nitrogen values above 100 mg. per 100 cc. only two had creatinine values below 8 mg., the lowest being 4.4 mg.; whereas, of the 14 patients with extrarenal azotemia with nonprotein nitrogen values above 100 mg. per 100 cc., 10 had occasional determinations in which the creatinine value was 8 mg. or less. Of six patients who had postrenal azotemia with the nonprotein nitrogen value above 100 mg., all had occasional creatinine determinations below 8 mg., one of which was below 4 mg. Although no diagnostically statistical pattern was discernible in the three groups, in general a creatinine value disproportionably low as compared to the nonprotein nitrogen increment is indicative of extrarenal or postrenal azotemia.

Of 14 patients with extrarenal azotemia with nonprotein nitrogen values above 100 mg., only four survived. Postmortem examinations in nine cases revealed the cause of death to be the primary disease or trauma rather than the secondary renal involvement, although undoubtedly the acute renal insufficiency was a major factor in hastening death. The essential features of the four surviving patients with extrarenal azotemia with nonprotein nitrogen values above 100 mg. are shown in the table. Quantitative phenol and xanthoproteic determinations on these patients will be reported in another communication.

COMMENT

The wide range of creatinine values in the extrarenal group is of interest. In one fatal case of nephrosis due to sulfonamides the nonprotein nitrogen rose to 352 mg. per 100 cc., at which time the creatinine value was 20 mg., while in another similar fatal case the nonprotein nitrogen value was 276 mg., at which time the creatinine level was only 7.4 mg. It is our impression that in extrarenal azotemia the creatinine and nonprotein nitrogen levels do not have the grave prognostic implications comparable values would have in primary renal disease. An illustrative case is that of S. P. in the table. The nonprotein nitrogen values reached 189 and the creatinine 16 8 mg. per 100 cc. At this point, the patient manifested such uremic symptoms as stupor and twitching. Yet complete recovery was effected 12 days later. Recently a number of reports of similar cases of reversible acute renal insufficiency have appeared in the literature.[10]

As can be seen in the table and chart of the four surviving patients, the creatinine value tends to drop toward normal levels more rapidly than the nonprotein nitrogen or blood urea nitrogen. Fishberg [2] has offered a reasonable explanation for the discrepancy between nonprotein nitrogen and creatinine in certain cases of extrarenal azotemia. He suggests that this is due to

[10] Peters and Van Slyke [9] Leff, I L; Rosenberg, B; Eisenmenger, W. J., and Steele, J. M · Recovery from Uremia: A Report of 5 Case, Am. J. M. Sc 217: 666 (June) 1949. Stock, R. J.: Acute Urinary Suppression: Observations in 22 Patients, Am J Med 7: 45 (July) 1949

the fact that urea is eliminated solely by glomerular filtration while creatinine is excreted by both filtration and tubular excretion. This would indicate that, although pathologically the tubules are primarily involved, in severe extrarenal azotemia the earliest effects may be on the glomeruli. Fishberg[2] also reports that he has observed this same phenomenon of increase in urea with normal creatinine in the first stages of mechanical urinary obstruction.

SUMMARY AND CONCLUSIONS

To determine the significance of the relation of creatinine to nonprotein nitrogen, we studied 44 cases of azotemia of a wide variety in the three general categories of primary renal, extrarenal and postrenal or obstructive uropathy. No diagnostically significant correlation between creatinine and nonprotein nitrogen was found in any of the three categories. Although the creatinine level may be increased in proportion to the nonprotein nitrogen elevation in all three categories, a creatinine value disproportionately low as compared with elevation of the nonprotein nitrogen is usually indicative of extrarenal or postrenal azotemia.

PHYSICAL MEDICINE AND REHABILITATION STUDY

One Year Report in Particular Relation to the Chronically Ill

NILA KIRKPATRICK COVALT, M.D.
Rocky Hill, Conn.

Seven hundred and ninety-seven patients were referred to the Department of Physical Medicine and Rehabilitation in its first year of operation, the first applied step in the study of rehabilitation for the chronically ill of this state. Patients were studied from July 1, 1948 to June 30, 1949 at the combined State of Connecticut Veterans' Home and Hospital and the Hospital for Chronic Illness, Rocky Hill, Conn., operated by the State Veterans' Home and Hospital Commission. The program is conducted under the auspices of the State Commission on the Care and Treatment of the Chronically Ill, Aged and Infirm, subsequent to studies which have been carried out by the State of Connecticut since 1938.[1]

PURPOSE AND ORGANIZATION OF THE STUDY

The 1947 survey revealed 15,000 chronically ill persons already under the care of one of the various state agencies. Forty per cent of these were under the age of 40; of the total, 40 per cent were bed patients. The commission wished to learn which members of this group could be made physically self sufficient or even returned to part or total economic usefulness and what plans must be made for the current and future care of the chronically ill in this state.

The state needed to know the type and extent of additional facilities necessary for the current case load and to determine what might have to be provided by the state, municipalities or private agencies. The first program was to be established in an existing facility and expanded to other municipal and private facilities as quickly as possible. Additional state construction was to be planned according to the needs demonstrated by this study.[2]

The program was started in the State Veterans Home and Hospital, where a five story unit of 328 beds and an enlarged surgical department had been completed in 1948 but had not been occupied. The older hospital unit included 284 beds, a domiciliary of 760 beds, a large auditorium, homes and dormitories for the medical, hospital and administrative staff and full maintenance shops.

Veteran residents of Connecticut who meet certain well defined admission requirements are eligible for admission to this home and hospital. They must enter through the hospital for a check-up, after which they may be discharged to the home—where they can stay indefinitely if they continue to meet the administrative rules. They may return to the hospital as outpatients for treatment of minor illnesses, and they are readmitted to the hospital as bed patients when necessary.

It was decided that the State Commission for Care of the Chronically Ill, Aged and Infirm could also admit a certain proportion of welfare patients to this hospital for medical evaluation, for any indicated medical or surgical treatment and for rehabilitation. These patients were to be nonveterans referred for care by one of the various state agencies. These patients could not be moved to the veterans' home but were to be returned to their own homes or to some convalescent or boarding home when treatment or training had been completed. The original referring agency would then resume responsibility.

Both veteran and nonveteran patients receive the same opportunity for treatment and training without any discrimination in status or segregation in the hospital. Administration is under the joint state and veterans commissions, and the combined facility is known as the Hospital for Chronic Illness. It will continue in the same facility until the entire bed capacity is needed by the veterans commission for its own patients or until the state commission builds its own facility.

The hospital serves patients with acute general medical and surgical requirements but is also able to care for those with lengthy and chronic illness. The fact that veteran patients can remain in the home and that patients receiving state aid can be kept here at no greater cost to the welfare department than that for their care in other institutions means that studies and treatment can be continued over long periods of time when necessary. This study in rehabilitation is not designed in the first instance to show the savings possible with a full program of physical medicine and rehabilitation, but it affords an opportunity to demonstrate what can be done when adequate time is available.

From the Hospital for Chronic Illness.

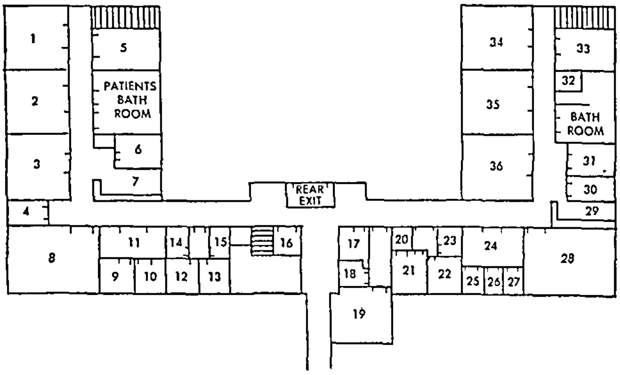
A program of physical medicine and rehabilitation must be based on a sound medical diagnosis. Many of the patients admitted through the joint state commissions need a complete medical evaluation. It is done routinely for all patients. It includes inspection and correction of dental, visual and aural difficulties in addition to any indicated medical or surgical treatment. The psychiatric, psychosomatic and social difficulties of each patient are considered as a necessary step to understanding the patient and his problems. Attending specialist consultants were added to assist the hospital staff in this evaluation and treatment.

There were approximately 250 patients in the older hospital unit when the Department of Physical Medicine and Rehabilitation officially opened June 1, 1948. The new wards were gradually opened until all the hospital beds were filled during the winter months. The domiciliary portion also filled to capacity during the same period, but about half its occupants left during the spring and summer of 1949. The turnover in acute illness is similar to that in other hospitals for the care of patients with acute general medical and surgical problems. The acutely ill as well as the chronically ill patients are included in this study.



Floor plan of the Department of Physical Medicine and Rehabilitation, Hospital for Chronic Illness, showing location of 1, power tools; 2, medium crafts; 3, light crafts; 4, photo laboratory; 5, print shop; 6, occupational therapy preparation room; 7, office space, 8, recreation, clinics and movies; 9 and 10, classrooms; 11, library; 12, 13 and 14, classrooms including speech therapy, vocal rehabilitation and education office; 15, occupational therapy office; 16, elevator; 17, staff dressing room, 18, elevator; 19, brace shop; 20, doctor's examining room; 21, doctor's office; 22, director of vocational education; 23, secretary's office; 24, staff room, 25, physical therapy office; 26, social service office; 27, recreation office; 28, gymnasium; 29, office space; 30, whirlpool bath; 31, Hubbard tub; 32, physical therapy class treatment; 33, peripheral vascular disease thermal control, and 34, 35 and 36, physical therapy treatments. The scale is 1/32 inch to 1 foot. There are approximately 10,000 square feet of work space, exclusive of corridors.

FACILITIES OF THE DEPARTMENT

The Department of Physical Medicine and Rehabilitation was assigned the entire first floor of the new unit—which had previously been designed for two bed and six bed wards totaling 64 beds—with two utility rooms and one day room on each wing, and one kitchen for the floor. The total bed capacity then became 584. Sixty-four of these beds are designated for ambulatory patients in the Department of Physical Medicine and Rehabilitation. Patients are transferred to these wards as a reward or for motivation, but they remain under the care of a ward physician. They have their own self governing organization. (The nursing staff is still too limited to place bed patients with special physical rehabilitation problems on these wards.) The first floor contains approximately 10,000 square feet of working space, exclusive of corridors. The entire space has been utilized, as is shown in the accompanying illustration.

One wing is assigned particularly to physical therapy; the other to occupational therapy, educational classes and prevocational testing and training. The day room on the physical therapy side is converted into a gymnasium; the other day room is used for clinics, variously scheduled meetings, recreation and as an overflow gymnasium or for occupational therapy. Two of the six bed wards on each wing are converted into offices and class rooms by the use of steel and glass removable partitions.

The physiatrist, who is chief of Physical Medicine and Rehabilitation, has an office with an adjoining examining room. There are smaller offices for the section supervisors and one for use of the counsellor from the State Department of Education, Division of Vocational Rehabilitation. Since all department records are kept in the staff room, the physical and occupational therapists do their charting together at a regularly scheduled hour every day. This further coordinates the work of the two sections and increases each therapist's understanding of the work of the other section. The physiatrist can easily hold joint staff meetings whenever indicated while the group is already regularly assembled.

Class rooms are used by the occupational therapists for handwriting classes; by the speech therapists for speech therapy, for lip reading and for making audiograms, and by the commercial instructor for typing and other commercial courses. The psychiatrists occasionally use a room for group work, as does the mental hygienist employed and assigned full time by the State Commission on Alcoholism (which is also conducting a study in the hospital).

The other wards have become treatment rooms. The entire department is equipped as completely as possible with every type of modern physical and occupational therapy equipment necessary for well rounded treatment as well as for teaching purposes. Two utility rooms are the occupational therapy preparation room and a photography laboratory and dark room; two rooms in the physical therapy wing contain the Hubbard tank and whirlpools. The bathrooms on either side are large, with the toilet facilities separated from the lavatories, showers and tub by a solid partition with an adjoining inner door. The bathtub on the physical therapy side is used for full tub hydrogalvanic baths. The patients are taught to wash their elastic bandages and the amputees their stump socks in the lavatories of that room. The occupational therapists teach shaving and shoe shining in the other lavatory. Self care toilet activities are taught in the two bathrooms by the male therapists, assisted by the department orderlies. The kitchen was turned into a brace and prosthetic shop where all adjustments, or even assembly, of braces or prostheses can be made.

Hospital patients are referred to the physiatrist by the ward or attending physicians. The ward physicians rotate sick call in the outpatient clinic held for the domiciliary members and refer patients from there. Special consultation forms have been provided for all department referrals. Every referred patient is assigned a physical medicine and rehabilitation department number in sequence as he is referred, and he maintains that number if he is readmitted to the department. A special symbol is added for each readmission. This numerical system makes it possible to know the total number of patients admitted to the department or the number of readmissions of any patient at a given time. It serves as an accurate statistical record which is always current.

The physiatrist assumes the full responsibility for writing prescriptions for all tests and treatment given in the Department of Physical Medicine and Rehabilitation. The hospital chart is reviewed. The physician examines the patient in the department whenever possible, on the ward when necessary. Examination in the department is preferred because gym trunks are provided. When the patient is dressed in these, the over-all body mechanics, posture, stance and gait can be more readily evaluated in terms of the whole man in addition to the specific physical complaint for which the patient has been referred. New patients can also be tested immediately for standing or walking in the parallel bars. All patients are questioned about previous occupations, work record and education in addition to the physical history. The social history is noted. The physical and occupational therapy supervisors are present at the time of the initial evaluation.

Many patients are referred originally for tests to assist in completing the diagnosis as well as for any treatment the physiatrist considers to be indicated. Other patients are referred as psychoneurotics. Many of these, as well as others without physical complaints, may be referred particularly for a prevocational evaluation or for possible reemployment through the State Department of Education, Division of Vocational Rehabilitation. The physiatrist most often additionally prescribes physical relaxation, heavy exercise or work therapy—or relaxing, stimulating or projective[3] occupational therapy for the psychoneurotic patients—as seems indicated by the psychiatrist's report. (Psychotic patients are transferred to other state or Veterans Administration neuropsychiatric hospitals.)

On June 30, 1949 the department staff included 10 physical therapists, 1 physical therapy technician, 7 occupational therapists, a part time speech therapist and a part time teacher of typing and other commercial subjects, 1 file clerk, 1 typist and 1 stenographer. The therapists are all graduates of schools approved by the American Medical Association.

TESTS AND TREATMENT

Therapists spend approximately one third of their time in making tests—particularly those which assist the physicians to confirm either a diagnosis or a prognosis. Manual muscle tests are routine when a patient has any muscle weakness irrespective of the cause. Electrical muscle tests are done to assist in confirming a neurological involvement and the degree of the reaction to degeneration. Range of motion is measured with a goniometer when there is any limitation of joint motion. Posture evaluation is recorded; hamstring shortening or expansion is measured on all patients referred for treatment of various respiratory difficulties. Oscillometric readings, skin temperatures and Gibbon and Landis tests are routine for any previously diagnosed or suspected peripheral vascular disease. When the neurosurgeon decides that a test sympathetic block is indicated, the anesthetist performs this procedure in the thermally controlled room in the department. A therapist does the appropriate tests before, during and after the block. All this group of tests are done by the physical therapists. The occupational therapists fill out an avocational questionnaire on every patient and do the first test in "Activities of Daily Living."

The special tests for "Activities of Daily Living" is routine for every patient with any disability. The patient is tested to see whether he is able to turn over in bed, handle all articles about his bed, handle all other common utilities, dress, feed and shave himself, get from the bed to either a sitting or standing position, and return. He is tested to see whether he can walk on level ground (and for what distances), climb curbs and ramps and finally climb stairs of various tread heights (with and without hand rails); also tested is his ability to get into automobiles and onto buses or other public conveyances and to cross streets with traffic lights. When canes, crutches, braces, prostheses or any other appliances are needed, he is instructed in their application and use and is graded accordingly. He is graded for what he can do initially and is then put in special training classes to become more proficient in the performance of these activities or to learn to do the things he is unable to do. Training in each activity continues and is graded separately until it appears that the maximum results have been obtained and that the patient is as physically independent as is possible within the limits of his physical and mental capacities. All grades are recorded on the patient's individual chart of activities of daily living.

This is functional treatment and training and it is done by both physical and occupational therapists. The occupational therapists conduct handwriting classes for all persons who need to relearn or improve their writing or to change their handedness. Occupational therapists also have shaving classes and teach all other activities that particularly relate to the use of the hands. The physical therapists assume the responsibility for the training in bed activities, sitting, standing, walking and traveling. This part of the program consumes about one third of the therapists' time and one third of the patients' total department prescription. Seldom is it sufficient for the total treatment of a patient, since definitive physical medicine procedures usually facilitate the functional recovery.[2b]

Definitive Treatment.—Definitive treatment in physical therapy includes specific muscle reeducation and therapeutic exercises (passive, active, active assistive and resistive) assisted by massage and various applications of heat, cold, light, water and electricity. Definitive treatment in occupational therapy uses projects for: increase of muscle strength, coordination or range of joint motion; prevocational testing, reconditioning, prevention of deconditioning and development of work tolerance; relaxation, stimulation or socialization, and creative art work—which may be of diagnostic assistance to the psychiatrist or may in itself be psychotherapy.[4]

Here as in any other well equipped Department of Physical Medicine there are at least 140 treatment possibilities in physical therapy, either as a single treatment or in combination. A similar number of treatment possibilities is available in occupational therapy—particularly since the physiatrist writes prescriptions according to the Licht nomenclature.[5] (The variety of treatment possibilities indicates the reason why physical medicine can serve all other fields of medicine and surgery.)

---

[3] Projective occupational therapy employs those arts which are unhampered by established technics and which allow for freedom of expression (such as finger or any other painting, clay or plasticene® modeling). It may include those arts with which the patient has no previous experience or preconceived ideas of technics.

[4] Hall, V. R.: Psychological Implications of Physical Medicine, Occup. Therapy **28**: 21-30 (Feb.) 1949. Harris, R. L.; Buvens, A. E., and Irwin, I.: Ceramics as Occupational Therapy for Patients with Suicidal Tendencies, ibid. **28**: 231-244 (June) 1949.

[5] Licht, S.: The Objectives of Occupational Therapy, Occup. Therapy **26**: 17-22 (Feb.) 1947.

Just as specific definitive treatment usually is prescribed to facilitate functional training for patients with chronic disabilities, capabilities of patients recovering from acute illness or injury are checked and functional training is instituted whenever indicated. For instance, treatment to regain motion in a leg after a hip fracture would be of little value if the patient were not taught to walk and climb stairs.

Definitive treatments prescribed for chronic disability are varied and may include one or several specific treatment combinations in accordance with the underlying pathologic, physiologic and anatomic conditions and the results of the diagnostic tests made in the department. Usually some form of both physical and occupational therapy is prescribed.

Much definitive treatment must be given individually, but definitive and functional treatment is done in groups whenever possible. Patients are grouped according to disabilities. Stimulation, motivation, learning by observation and even competition often speed accomplishment. Patients with cardiac diseases are often grouped for graded exercises, as are patients with asthma or those with various other conditions who need to be taught physical relaxation. Patients with arthritis have a daily group exercise class, irrespective of any other individual prescription. In such classes individual patients are encouraged to take turns in giving the exercise commands for the group while the therapist goes from patient to patient, giving individual supervision. The hemiplegia classes are conducted similarly, and the patients enjoy mat and wand drills or reciprocal motion exercises done to music in this fashion. The patients enjoy their fellow patient's instructions—sometimes laughing heartily at or with the instructor—and work with more individual concentration, pending the time when it will be their turn to instruct.

Functional Activities.—Functional activities are taught in similar groups: Class A includes all activities in bed, getting from the bed to a chair or to a standing position and all the hand activities. Class B includes all activities that have to do with the accomplishment of independent walking on level ground. Class C includes all "climbing" activities and the final training in traveling outside the hospital. Patients are divided by disabilities into three main groups, and the classes are subdivided accordingly. The hemiplegic patients work together; those with other neurological disabilities form a second large group, and the amputees are the third group, subdivided into units for preprosthetic and postprosthetic training.

One occupational therapist and one physical therapist work together in the class A activities, giving an hour daily to each disability group. This is done in one large treatment room containing eight beds. The occupational therapist has an additional class each day for more practice in hand activities. This class is continued until hand training is completed, even though the patient is walking. Class B and class C work is conducted by the physical therapists in the gymnasium, in the halls and on the stairways. Patients usually respond better to the group work and are more interested. In addition, a staff of limited size can handle more patients with efficiency.

The speech therapist has individual and group therapy for the aphasics, the stutterers and the stammerers. The aphasics constitute the largest group and average 15 to 20 at all times. Every gain in vocabulary is most gratifying to the patients, because the sense of frustration of these persons is severe, no matter how much physical restoration is accomplished. The handwriting classes are often adjunctive to speech therapy. Esophageal speech is being taught by an occupational therapist instead of by the speech therapist—for the only reason that the occupational therapist has had special training in that procedure.

The speech therapist also has had some training with the deaf and hard of hearing; she is doing routine testing and is teaching some lip reading under the supervision and prescription of the ear, nose and throat specialist who is the director of the aural rehabilitation program. This program was just getting started at the end of the first year. In order to determine the case load and treatment needs in aural rehabilitation in this hospital, it was decided that every patient referred to the Department of Physical Medicine and Rehabilitation automatically would have a hearing evaluation. Audiosweeps are now done on each patient. When a hearing loss is indicated an audiogram is done. The staff of the ear, nose and throat service examines each of these patients, treats them and orders sinus roentgenograms, if indicated. Hearing aids and training in their use will be added as quickly as possible. Addition of a soundproof room and other necessary equipment is contemplated. More personnel will be necessary later. The present speech therapist will soon be employed full time.

Educational Program.—To date the business courses are the principal part of the anticipated educational program. This educational therapy mainly is prevocational testing and training. Unless a patient is being kept in condition to return to an office position, the majority of the patients will have to complete their training in business schools. A few patients have been taught one-handed typing; one of these is a 55 year old hemiplegic who is now attending a business college under the auspices of state vocational rehabilitation. Two severely paralyzed patients now have a means of communication—as well as therapeutic exercise—by having been taught to use special machines, one a remote control typewriter and the other an electric typewriter. A third patient is just starting such training. So many patients need or want this type of educational training that the instructor will soon be employed full time.

A more complete educational program is contemplated but cannot be developed until a full time director of educational and prevocational training can be added to the staff. Courses for high school equivalency diplomas are contemplated.[6] The present photography and print shops, now under occupational therapy supervision, will be expanded; the maintenance shops on the grounds can probably be utilized more fully.[7] One patient is now in charge of the photography shop and assists an occupational therapist to make movie and still pictures of the patients and of department activities. A hospital newspaper is reported, written, mimeographed, assembled and distributed entirely by the patients. The patients cut stencils for the paper and for any other material that is mimeographed in the department. A hand printing press is being assembled; a multigraph duplicator is being renovated.

Recreation.—There is, as yet, no recreation director. The physical therapists, and particularly the occupational therapists, have combined as much of a recreation program as is possible with their other duties. As a temporary solution one afternoon a week is set aside for recreation instead of regularly scheduled treatments. Usually the occupational therapists are responsible for this program while the majority of the physical therapists are doing diagnostic tests. Indoor games and contests are conducted in the day room. In good weather croquet, volley ball, horseshoes and shuffle board are played outdoors. Three outside doors open on an area where these activities are easily accessible.

[6] General Educational Development Tests: High School Level, in Medical Rehabilitation Programs, VA Hospitals, Veterans Admin. Techn. Bull., TB 10A-20 (Feb. 15) 1947.

[7] Prescription for Work, United States Veterans Administration, Department of Physical Medicine, Medical Rehabilitation Service, 1946.

There are occasional evening parties in the day room on the rehabilitation wards. Patients on those wards are hosts to the nurses, the therapists and other hospital patients who are active in the Department of Physical Medicine and Rehabilitation. Dancing is the main entertainment. Music is furnished by a (volunteer) professional dance orchestra. The patients have their own committees to plan other entertainment, decorations and refreshments. The physical medicine and rehabilitation staff members sponsor and supervise the party.

A softball diamond was completed during the summer of 1949. Hospital and domiciliary patients are eligible both to play and to be spectators. Although the softball playing was managed from the veterans home and was not part of the Department of Physical Medicine and Rehabilitation, it was of great value to many patients in that department.

DISEASE OR DISABILITY CLASSIFICATION

Table 1 attempts to classify the 797 referred patients according to their disease or disability. The patients referred in the first year are shown in the admission column; those remaining under treatment at the start of the second year appear in the next column. They have been grouped and tabulated by specialties as far as is possible. It is obvious that those disabilities or diseases marked with asterisks, or totalled separately, might fall into any of the larger specialty groups, depending on the diagnosis and indicated treatment for each patient. The classification is an arbitrary one for department convenience in particular relation to disability and treatment. A patient with more than one of the diseases or disabilities included in this classification was scored for each. The additional scoring totaled 910 disabilities or diseases among the 797 patients referred: for example, several unilateral amputees had peripheral vascular disease in the remaining leg; two amputees had residuals from cerebral vascular accidents, as had some of the cardiac patients and one patient with epilepsy; some psychiatric patients had various physical disabilities. Three hundred and thirteen of the total referred patients had disabilities which made them totally or partially incapable of self care; they were referred for this training. The cause and duration of each of these conditions as well as the additional diagnoses or pathological conditions—such as diabetes, hypertension, cardiac disease, gastric ulcers or hernias—were noted by the physiatrist. That information was recorded on the individual department charts and on prescriptions written by the physiatrist for the staff of the Department of Physical Medicine and Rehabilitation.

These referrals confirm the fact that a department of Physical Medicine and Rehabilitation serves every other field of medicine and surgery. Such a department is no more a subdivision of orthopedics or of neurology than it is of psychiatry, general medicine or general surgery. It parallels all. Referrals from general surgery—particularly abdominal surgery—are lowest in this group for only one reason, a shortage of therapy staff. A choice of treatment by disabilities had to be made because of the large number of referrals. The chief of surgery and the chief of physical medicine and rehabilitation are in agreement on the importance and need for this treatment, and it is a standing referral request, pending the time when more therapists are available. When that treatment can be given here routinely, approximately one fourth of the total referrals will probably be from the general surgical service, considering how much surgical treatment for acute conditions is being constantly done in this hospital. I have previously stressed the importance of such treatment [8] and continue to be of the same opinion.

TABLE 1—*Classification of Patients Referred to Department of Physical Medicine and Rehabilitation*

Disabilities or Disease Syndromes Referred for Treatment 6/1/48 to 7/1/49	Admissions 6/1/48 to 7/1/49	Patients Still Under Treatment at Start of Second Year	Total Disabilities, Divided by Specialties, When Possible		
Hemiplegia*	77	18	77	Total neurological 209	77
Multiple sclerosis	22	13	All other neurological 132		
Spinal cord injury	6	3			
Parkinson's disease	18	2			
Amyotrophic lateral sclerosis	9	2

Total disabilities	910	212			
Total patients referred	797				

* Those disabilities or diseases marked with asterisks or totalled separately might fall into any of the larger specialty groups, depending on the diagnosis and indicated treatment for each patient.

This classification clearly indicates that patients cannot be separated by specialties if they are to be rehabilitated. Other classifications would no doubt give the same indications. Disability becomes the common denominator. It is the basic concept of physical rehabilitation and total rehabilitation that a patient must learn to live with, and not for, his disability if he is again to become a well adjusted person to any partial or total degree; medical responsibility for each patient is not over when the definitive medical and surgical treatment is complete and the acute phase of an illness has been passed. One must consider the total man and his psychiatric, social and economic adjustment as well as his physical readjustment or retraining.[9]

---

[8] Covalt, N. K. Bed Exercises, Arch. Phys. Med. **28:** 18-29 (Jan.) 1947. Early Exercise for the Convalescent Patient. Modern Program of Bed Exercise Prevents Deformities Due to Illness or Injury, Improves Morale, and Hastens Recovery, Am. J. Nursing **47:** 544-546 (Aug.) 1947.

These patients were referred for preventative treatment, for diagnostic and prognostic tests and for definitive and functional treatment. Treatment was given during acute illness, in the convalescent period and in chronic illness or that in which the residual chronic disability had oftentimes persisted for many months or years. Preventative medicine included such procedures as correct bed positioning to prevent deformities in the early stage of acute illness and early training in self care to prevent physical helplessness after an acute illness—particularly an illness which of itself might be considered to be chronic or progressive. It is apparent that there is no disease or disability that cannot benefit during some phase by some form of physical medicine.

TREATMENT AND RESULTS

Of the 797 referred patients, 27 did not need treatment, 313 (including 64 belonging to the group of chronically ill, aged or infirm) needed functional training, 434 needed definitive treatment only and 23 required only vocational placement. There were many patients among the veteran group already in the hospital when the program started who needed functional training—including 41 hemiplegics and 17 amputees, not one of whom could walk. Many patients among both the chronically ill and the veteran groups had been physically dependent for two to five years and longer. The State Commission admitted a total of 129 patients in the first year. All of these were evaluated by the Physical Medicine and Rehabilitation Department.

During the first year 23 patients had acute disabilities after orthopedic procedures. In the remaining 299 patients of the 313 requiring functional training the disabilities were of relatively long duration with the exception of a few recent cerebral vascular accidents and a few recent amputations. Of the entire 313, some were bed patients and others were confined to wheelchairs. Many were unable to feed, dress and bathe themselves or to handle any other ordinary utilities. The few who could walk were insecure or unable to take more than a few steps on level ground, even with crutches or canes. Activities of Daily Living tests were made on these patients immediately after referral, and functional training was instituted. This was started at the bedside, if necessary.

Fifty-two patients with disabilities absolutely refused treatment; some refused to even try the Activities of Daily Living test. The first several refusals were not accepted. Repeated attempts were made to motivate each patient, and the physiatrist insisted that repeated attempts be made up to a minimum of three months' trial—unless it became absolutely obvious before that time that nothing could be done. The psychiatrist interviewed each of these persons, as they have attempted to interview all other patients. Psychotherapy was attempted whenever feasible. The referring physician and the nursing staff added their encouragement. Some patients in this group signed themselves out of the hospital shortly after admission. Many of the 52 were in the younger age group.

Eight other patients referred for evaluation were too senile or deteriorated to receive any treatment. In 23 others treatment was discontinued after a minimum trial treatment of no less than three months; for the majority treatment was continued six to 10 months. Two patients voluntarily requested resumption of treatment. The remainder are almost all in the hospital. About every three months the ward physician requests that the department try again to teach them self care activities. This is always done—so far without results.

The group of 23 patients represents the only complete failures among 253 patients who have actually had training in functional self care. The majority of these have learned to walk, climb stairs and travel outside the hospital. A small percentage will always be wheelchair patients and are considered to have reached their maximum goal in physical rehabilitation. Eighty-one of the group were still under training at the start of the second year, but complete physical independence was considered to be possible for all of them.

LENGTH OF TREATMENT PERIOD

There has been an opportunity to spend unlimited time on many of these patients, and that time has been invaluable. As an example, 49 amputees were referred to the department, including the 17 who were here when the program started. (One of the 17 died shortly after the department opened.) Thirty-three patients have been fitted with prostheses. Except for two, to my knowledge all are (or should be) walking today. One amputee, aged 46, had to be transferred to a psychiatric hospital eleven months after the department opened; the second, fully trained, died of a coronary attack two months after discharge. He had no evidence of any cardiac disease while in the hospital. Necessary (and frequent) changes in the prostheses, particularly the sockets in relation to stump shrinkage, were made in the prosthetic shop so that patients were discharged from the department with well fitting prostheses, with a knowledge that changes could still occur and with arrangements made for further revisions or changes. It took six to nine months to train some of these persons. Most of these, as well as the 15 who did not receive prostheses, had three months' preliminary training. Three of the 15 were mentally incapacitated; the other 12 lacked the motivation, and particularly the motor skills, necessary to use a prosthesis. This latter group, almost without exception, were made physically independent either in wheelchairs (if bilateral amputees) or by the use of crutches. The majority of all the amputees were over 60 years of age.

Braces were furnished to 45 patients, the majority of these with residuals of a hemiplegia. Of 77 such patients admitted, the majority are now walking. Approximately 50 per cent of patients with this disability required braces.

It has been learned that one should not make a final evaluation of a patient's status and decide that physical rehabilitation is impossible until he has been offered a minimum of three months' training. Judgments made at the time of the first examination or in the first week must often be changed. It may take three months to motivate a patient, to overcome his "mental atrophy of disuse,"[10] or to differentiate between mental disuse atrophy and mental deterioration. He must be convinced that it is worth while to make the effort. Fear must be overcome. Fear of the patient may be due to previous warnings concerning the danger of any physical activity or may relate to the security and the attention he will receive if he remains in bed. Helplessness can often be for secondary gains (the advantage the patient derives from his illness).[11] Psychiatric evaluation and guidance is most helpful during this period. It is often equally necessary for the occasional patient who starts retraining with enthusiasm and quickly reaches a plateau without having attained the maximum accomplishments which appear physically possible.

[9] Rusk, H. A.: The Broadening Horizons of Rehabilitation and Physical Medicine, Arch. Phys. Med. **30**: 26-28 (Jan.) 1949; Dynamic Therapeutics in Chronic Disease, Postgrad. Med. **5**: 278-287 (April) 1949.

[10] Mental atrophy or disuse occurs when a patient has had no mental stimulation or has made no effort to concentrate or to think but has been content to placidly vegetate.

A clearcut statistical report of discharges cannot be made for many reasons. Many veteran patients continue to live in the hospital or domiciliary because they have no other home. Some of these with disabilities, who have become capable of all the activities of daily living, are continued on partial treatment or are rechecked in the Department of Physical Medicine and Rehabilitation to prevent physical deconditioning and to maintain interest (particularly in occupational therapy).

STATUS OF PATIENTS AT START OF SECOND YEAR

Of the 797 patients referred, 244 remained under treatment at the start of the second year, including the 81 with disabilities. Some of the 244 represent readmissions, particularly among the veterans—since some reasons for readmissions are peculiar to this institution. Veteran patients are discharged from the home and hospital for infringement of administrative rules. Usually, they can be reinstated within 60 to 90 days. Many veterans leave against medical advice; others in the home just leave—usually to try to be employed. If a job is not available they often return because legally this can be their home.

TABLE 2.—*Partial Recapitulation of Discharges*

Evaluation, no treatment indicated	27
Physical rehabilitation considered possible, treatment refused	52
Treatment discontinued for other reasons, usually medical complications	69
Trial treatment, physical rehabilitation, failed (three of group died)	23
Total deaths after treatment discontinued	24
Transferred to other hospitals (usually tuberculosis sanatoriums or psychiatric hospitals)	24
Discharged without informing the Department of Physical Medicine and Rehabilitation:	
Improved or (possibly) maximum results obtained	162
Unimproved or treatment incomplete	134

In the early months of the program some patients were discharged by the ward physicians before treatment in the Department of Physical Medicine and Rehabilitation was complete because those physicians, like many others, were accustomed to discharge all patients as soon as definitive medical or surgical care was complete.[12] These physicians had to become conscious of total care—including physical rehabilitation—with total rehabilitation as the ultimate goal. This was more often true of patients requiring definitive physical medicine than of patients requiring physical rehabilitation.

A maximum of 172 patients representing 216 disabilities in my opinion have achieved the maximum of self care. There were failures with 23 patients, approximately 15.5 per cent of the 290 with chronic disabilities; there were 43 per cent failures if the 52 patients who refused treatment are also taken into consideration. There were no failures among the persons with acute disabilities, which included those with early cerebral vascular accidents and amputations in addition to the 23 patients with orthopedic disabilities (table 2).

SUMMARY

I have given a general outline of the purpose and organization, personnel and physical facilities of a Department of Physical Medicine and Rehabilitation which has been established as part of a study concerning treatment of the chronically ill in the state of Connecticut. The types of patients referred to the department are discussed in general.

The 797 referred patients have been classified as far as is possible by disabilities, which appear to be the common denominator in planning a program of physical and total rehabilitation. A total program considers the physical, psychological, social and economic adjustments of each person in order to utilize his remaining capabilities to the greatest extent, regardless of a residual physical disability.

It would appear from this report that definitive and functional physical medicine are needed concomitantly and that such treatment, planned or started at the onset of an acute illness, can prevent the development of chronic disabilities which lead to helplessness in the vast majority of cases. It is an excellent form of preventative medicine. The association of patients with acute illness which could result in disabilities and patients with chronic illness has served as a motivating factor for those in each group.

In this study the number of chronic invalids who failed to accomplish any part of functional self care activities is approximately 15 per cent. The majority have all learned to walk with at least a fair degree of proficiency. Age has not been a determining factor. Adequate time for training has been important. A minimum of three months has been considered most necessary. Physical rehabilitation would have been impossible for many persons if all efforts to aid them had been discontinued before the end of this time. Six months to a year (or more) has been taken to complete training for some of these patients. The psychological factor, particularly relating to fear, secondary gains or motivation, has to be especially evaluated during the early period of rehabilitation. The time that should be spent on each patient in relation to the law of diminishing returns can only be evaluated after much more study. Since adequate time and hospital facilities have been available, my associates and I are impressed with the total number of patients with long-standing disabilities who can again be made physically independent. The lack of future economic productivity of some of these persons must be balanced against the time that others formerly consumed in their care.

A department of physical medicine and rehabilitation can offer service to every other field of medicine and surgery. There appears to be no disease or injury at some stage of which the patient cannot benefit by treatment in such a department. The many facets and ramifications of such a department make it the coordinating center for the entire program of rehabilitation, but every member of the medical staff and all ancillary services—both inside and outside the hospital—must be part of the team. A sound medical diagnosis and treatment is the foundation of any part of rehabilitation, but it is the whole patient and not his disease which is to be rehabilitated.

LICENSURE REQUIREMENTS FOR THE PRACTICE OF PATHOLOGY

GEORGE E. HALL
Chicago

In considering the legal requirements of the practice of pathology, two questions naturally arise. First, does a person who carries out the activities of a pathologist really practice medicine? Second, if he does, does he do it in such a way that he brings himself within the purview of the medical practice act of his state so that he must be licensed to practice medicine?

What is pathology and what does a pathologist do? Most dictionary definitions of pathology define it as a branch of medicine which treats of the structural and functional changes caused by diseases. In states having basic science acts, pathology is named as one of the basic sciences along with bacteriology, anatomy and chemistry. None of the last-mentioned sciences, however, are defined as being branches of medicine. They are all defined as sciences, i. e., the science which treats of bacteria, the science of the structure of the body, and the science which treats of the elements and atomic relations of matter. Why this difference? There are, it seems to me, two meanings of pathology just as there are two generally accepted meanings of the term practice of medicine. In its narrow sense, medicine, or the practice of medicine, is the art or science of healing diseases by the administration of internal remedies. In its broader sense, the practice of medicine means the whole field of curing diseases and includes the use of drugs or surgery or any other means which might be necessary. So it is with pathology. In a narrow sense pathology has a purely academic meaning. It is just one of the subjects taught to medical students, just one of the basic sciences. In this sense it is certainly not the practice of medicine. In its broader meaning it is the practical application of a science in such a way that physicians and surgeons are enabled more adequately to determine on the course of treatment they will follow with regard to a particular patient. Even in this broader sense, however, there are two separate and distinct types of activity engaged in by the pathologist. Suppose, for example, that all a pathologist does in a particular case is report a blood count. This is merely a mechanical procedure which a technician can do with proper training. No professional decision or opinion is given. I do not feel that such an act is the practice of medicine, but it is one phase of the practice of pathology. Suppose, however, that the pathologist not only reports the blood count but states that in his opinion, based on an examination of the blood and an examination of a frozen section of tissue from the spleen, a particular person is suffering from leukemia. Such conduct would obviously seem to constitute the practice of medicine. What is the difference? In the latter case the pathologist not only performed a pathological technic, he used the knowledge gained from study and experience to furnish an opinion, a diagnosis if you please, concerning a particular patient and such diagnosis formed the basis for medical treatment. I therefore believe that the practice of pathology is the practice of medicine when pathology is defined in its broader sense and when the acts of the pathologist consist of the rendering of an opinion or diagnosis based on study and experience at the request of a physician or surgeon and with reference to the treatment of a particular person. The crux of the situation is the diagnosis. It is the diagnosis which lifts the pathologist out of the classification of a highly trained and competent laboratory worker and places him in the field of the medical practitioner. It is the diagnosis, made at the request of the physician in charge of a case, which imparts to the pathologist a share of the physician-patient relationship in the same way that a fellow surgeon or internist or radiologist might be called on for assistance. That the practice of pathology in this way is the practice of medicine is not my personal opinion alone. It is also the opinion of the House of Delegates of the American Medical Association and has been since as long ago as 1943.

Now, bearing in mind that when a pathologist diagnoses he practices medicine, do the medical practice acts require licensure of one who diagnoses disease? Each medical practice act contains some phraseology which indicates the conduct which is included as the practice of medicine in that state. In Louisiana and Oregon there can be no doubt but that a pathologist must obtain a license to practice medicine. In Louisiana the definition of the practice of medicine includes the examining of a "person or material from such person" for the purpose of diagnosing, treating and curing. In Oregon the word diagnose is defined to mean "to examine another person in any manner," and it is further provided that "it shall not be necessary that the examination be made in the presence of such other person, it may be made on information supplied either directly or indirectly by such other person." Twenty-two other states (Arizona, California, Colorado, Connecticut, Delaware, Florida, Georgia, Idaho, Illinois, Kentucky, Maine, Michigan, New Jersey, New Mexico, New York, North Carolina, Ohio, Pennsylvania, Rhode Island, South Carolina, Utah and Virginia) and the District of Columbia include the word diagnosis, prognosis or examination within their definitions of the practice of medicine. Thus a pathologist who does diagnose must be licensed in those states. In Arkansas, Massachusetts, Nebraska, Nevada and Tennessee the medical practice act makes it unlawful to practice medicine or any of its branches without a license to practice medicine. If one accepts the definition of pathology as a branch of medicine, then pathologists must also be licensed in these five states. Thus there are 29 states in which, I believe, a pathologist practicing pathology in the broad sense and as an aid to medical treatment must be licensed to practice medicine.

This leaves 19 states in which the medical practice acts do not use the word diagnose or examine, or any similar expression in their definition of the practice of medicine. Of these 19 states, however, 17 (Indiana, Iowa, Kansas, Maryland, Minnesota, Montana, Missouri, New Hampshire, North Dakota, Oklahoma, South Dakota, Texas, Vermont, Washington, West Virginia, Wisconsin and Wyoming) contain provisions requiring the licensure of persons who hold themselves out or publicly profess to be physicians or who advertise that they are authorized to practice or who call themselves M.D.'s. Thus if a pathologist signs himself M.D. or Doctor and carries a listing in the classified directory under Physicians and Surgeons and lets himself be publicly referred to as a physician, I think he must be licensed in those states. I do not mean to imply, however, that if he in no way holds himself out as a

---

Staff Associate, Bureau of Legal Medicine and Legislation, American Medical Association.

Read at the Annual Meeting of the College of American Pathologists, Chicago, Oct. 16, 1950.

practitioner of medicine he therefore need not be licensed merely because the medical practice act omits the word diagnosis from its definition of what constitutes medical practice. In most cases, such definitions were formulated many years ago and were merely intended as a general description of the usual scope of activity of a doctor. No need for a detailed and precise definition existed. When such definitions are subjected to judicial scrutiny, the omission of the word diagnosis is not necessarily important. In Iowa,[1] for example, one of the 17 states just mentioned, the Supreme Court has said that manifestly the first duty of a physician to his patient is to diagnose his ailment and that one who publicly professes to be able to diagnose human ailments and to prescribe treatment therefor is engaged in the practice of medicine within the meaning of the law. And in Minnesota,[2] another of the 17 states, the Supreme Court said that the science of diagnosing human diseases and ailments has come to be a distinct branch of the medical profession. The diagnostician limits his efforts to the discovery of the disease or ailment, leaving treatment to some other physician or surgeon. A physician who thus applies his learning and energies in the diagnosis of disease, the Minnesota court concluded, is engaged in the practice of medicine even though he prescribes no drugs and administers no specific treatment. Supreme Court decisions in Indiana,[3] Kansas,[4] Missouri [5] and Tennessee [6] also emphasize diagnosis and examination as being integral parts of the practice of medicine.

This leaves two states (Alabama and Mississippi). In these two states the medical practice act does not specifically require licensure of those who merely hold themselves out as practitioners. It does not specifically require licensure for practicing any branches of medicine in addition to medicine itself, as do medical practice acts of Massachusetts, Nebraska and of the other states. It does not use the word diagnose. A practitioner is defined as one who prescribes for treatment or who treats or offers to treat. Here also, however, one must not jump to the conclusion that a pathologist need not be licensed. The definition is still subject to judicial interpretation, and the courts of both of these states have, in fact, already considered the problem. The Supreme Court of Alabama [7] has said that, in common parlance, treatment is the broad term covering all the steps taken to effect a cure of the injury or disease. It includes examination and diagnosis as well as the application of remedies. The Supreme Court of Mississippi [8] has held that a person who looks at people and tells them their physical ailments and prescribes or sells medicines on such diagnosis is engaged in the practice of medicine regardless of the source from which he claims the power to diagnose.

To recapitulate, the definitions of the practice of medicine found in the medical practice acts of 29 states are sufficient, in and of themselves, to require the practicing pathologist to obtain a license from the medical examining board. In the other 19 states, although an apparent doubt might exist concerning the need for licensure because of the absence of a sufficiently detailed statutory definition of medical practice, such doubt may be removed by a judicial decision construing the existing definition. In the eight states in which such decisions already exist, it is clear that diagnosis is an essential element of medical practice and that practicing pathologists must be licensed. In my opinion these decisions are well reasoned, and I have little doubt but that they will be followed in the other 11 states when the question is raised.

Clinical Notes, Suggestions and New Instruments

PHLEGMASIA CERULEA DOLENS

Massive Venous Thrombosis in an Extremity Associated with Shock

SAMUEL PERLOW, M.D.
Chicago

Phlegmasia cerulea dolens, or "blue phlebitis," is an acute fulminating form of deep venous thrombosis first described by Trémolières and VéRan [1] in 1929. Clinically there is sudden severe pain in a part of an extremity which quickly spreads to involve the whole limb. This is associated with pronounced edema of the foot and leg and later of the thigh. The most striking change is the severe cyanosis and the purpuric areas and petechiae which develop early and produce a most alarming picture. The limb becomes numb and cold, and the peripheral pulses disappear. Associated with these local changes there is rapid development of circulatory collapse and the clinical picture of shock. In the severer cases death results. In the less severely affected patients who survive, the disease follows the usual course of iliofemoral venous thrombosis with gradual disappearance of the edema and the purpuric areas and return of the arterial pulsations, sensation and warmth to the extremity.

In 1941 my associates and I [2] produced a similar condition in experimental animals. Extensive venous thrombosis of a hindleg was produced by ligation of the major veins and then intravenous injection of a carbon suspension in a retrograde fashion. In each instance massive edema and purplish discoloration of the extremity developed along with tachycardia, progressive drop in blood pressure and hemoconcentration. Extreme shock due to fluid loss and death followed in 87 per cent of our experimental animals. The increase in weight of the edematous hindquarter over the contralateral one varied between 4 and 6.1 per cent of the total body weight and was equal to 50 to 75 per cent of the calculated blood volume. Zimmermann and de Takats [3] have shown that such edema fluid may have a protein content of 1.25 to 3.4 per cent.

Muscle biopsies from the edematous extremity revealed early a distention of the capillaries and the presence of edema fluid in their vicinity and later thrombosed small and large veins along with hemorrhage between the muscle fibers and in the areolar and subcutaneous tissue. Postmortem examination showed that almost all the major and collateral veins in the extremity were thrombosed. The suprarenal glands revealed varying degrees of hyperplasia and microscopic hemorrhages in the zona fasciculata. There was pronounced dilatation of the central veins and sinusoids of the liver and occasionally dilatation of the capillaries of the lungs and of the intestinal mucosa.

From the Department of Surgery, Michael Reese Hospital.

[3] Zimmermann, L. M., and de Takáts, G.: The Mechanism of Thrombophlebitic Edema, Arch. Surg. **23:** 937 (Dec.) 1931.

In follow-up experiments[4] we found that limitation of the loss of fluid into the involved extremity by preliminary administration of desoxycorticosterone acetate or mechanical limitation of the edema of the limb by a plaster cast prevented shock in most instances and the animal survived Aside from the less pronounced edema of the tissues of the extremity the other changes were essentially the same Our experiments also indicated that the development of shock following venous thrombosis depended not so much on the amount of the plasma fluid loss but rather on the rate at which it is lost Some of our experimental animals survived when the fluid loss into the tissues was slow even when the amount lost was as great as in those animals that died of shock

These experiments illustrated that an extremely large amount of fluid and blood can be lost into an extremity when its venous channels are almost completely occluded and may be sufficient to result in shock and death It seemed to us that on rare occasions extensive thrombosis of the veins of an extremity in man might lead to death in a like manner

Since our original experiments we have seen a number of patients with pronounced edema of an extremity following deep vein thrombosis In all of those patients the edema developed slowly, over a period of several days, and, although there was mild hemoconcentration in a small number, no signs of shock developed, which indicated again that gradual fluid loss by edema does not produce shock Recently, however, we observed a patient with a clinical picture which was similar to that seen in our experimental animals

REPORT OF CASE

J K, a 40 year old woman, was admitted to Franklin Boulevard Hospital on the service of Dr S Berger on Feb 28, 1949, because of bloody diarrhea of several weeks' duration A diagnosis of amebiasis was made after a complete physical and laboratory examination, and she was given specific therapy Improvement was slow

On March 25, one month after her admission to the hospital, a sudden severe pain developed in the left leg and thigh which was quickly followed by massive edema of the extremity to the groin and the development of extensive purpuric areas and numerous petechiae throughout the extremity Associated with these local changes, a rapid thready pulse, pronounced perspiration, an anxious facies and extreme weakness developed When she was seen in consultation about four hours after the onset she seemed to be in severe shock The left lower extremity was greatly edematous to the groin, the diameter measuring about one and a half times that of the right It was cold and cyanotic and covered with extensive purpuric areas The arterial pulsations were absent in the involved limb, and the oscillometric measurements in the calf were zero Blood examinations revealed a hematocrit reading of 70 per cent Rough calculations from our measurements indicated that between 4,000 and 5,000 cc of fluid was lost into the tissues of the left lower extremity

Treatment consisted essentially of replacement of blood, plasma and fluids for the shock and lumbar sympathetic blocks to overcome the arterial spasm and the danger of gangrene Anticoagulants were not used because of the danger of bleeding from the bowel The following day the patient was greatly improved and out of shock The hematocrit reading was 38 per cent The extremity was warm, and the arterial pulsations had returned but the edema and the discoloration remained unchanged for about four days and then began to clear up fairly rapidly On April 1 the patient was taken home, the appearance of the extremity had improved, and the diarrhea was controlled

On April 11 she was admitted to the Cook County Hospital for further treatment of the amebiasis There was little residual edema of the left extremity, and the purpuric areas had almost completely disappeared On April 13 sudden massive edema of the right lower extremity associated with extensive purpuric areas developed over the whole limb and the lower right portion of the abdomen and the right buttock, along with general signs of shock She was given 1,000 cc of plasma intravenously but died three days later The left extremity, which had been involved previously, remained unchanged during this episode

Postmortem examination revealed massive thrombosis of both iliac and femoral veins, severe ulcerative colitis, brown atrophy of the heart, acute splenitis, ulcerative chloecystitis and cholelithiasis and cloudy swelling of the kidneys There was no peritonitis or extension of the inflammation of the bowel to the veins

In 1948 DeBakey and Ochsner[5] were able to find only 32 cases of "blue phlebitis" in the literature and added one case of their own Of the reported cases eight, or 25 per cent, terminated fatally Most of the patients were adults, and in only a small percentage was the condition associated with prior surgical treatment In two patients an upper extremity was involved In five of the cases reported and in our case the condition developed while the patient was being treated for some form of ulcerative colitis There is no known cause for the extremely rapid thrombosis of the veins that occurs The extensiveness and rapidity of the process seem to indicate a different pathogenesis from that of the type of thrombophlebitis usually seen DeBakey and Ochsner suggest that some unknown changes in the mechanism of blood coagulation in those patients associated with reflex arterial spasm and slowing of the blood flow may be factors in its development Postmortem studies reveal that the venous thrombosis is extensive and involves not only the major veins but the small venules Biopsy of the tissues from our experimental animals showed similar extensive involvement occurring within a few hours of the onset

In addition to the cases reviewed by DeBakey and Ochsner, we were able to find five more cases in the recent literature In a discussion of a paper on venous thrombosis in 1940 Phemister[6] described a woman with pronounced edema of an extremity who died in shock in 24 hours At autopsy a fresh thrombus was found completely blocking the common iliac vein From measurements of the limbs it was calculated that the volume of the involved extremity was about 4 liters greater than that of the other, and it seemed that the immediate cause of death was shock due to fluid loss

Dennis[7] in 1945 reported a case of acute circulatory collapse after a common femoral vein ligation for postoperative venous thrombosis which was treated successfully with blood and plasma transfusions Morgan, Allen and MacCarty[8] recently reported three cases of acute peripheral circulatory failure caused by acute venous thrombosis In the one patient who recovered they calculated that approximately 4,255 cc of fluid had been lost into the limb In this patient the peripheral arterial pulsations were absent for 40 hours and a pronounced anemia developed along with transitory azotemia, which they believe was due to absorption of extravasated blood and diminished renal blood flow during the period of peripheral circulatory failure

SUMMARY

A case of "blue phlebitis" is reported There was massive involvement of first one and then the other lower extremity with an estimated fluid loss of 4,000 to 5,000 cc into the left Blood, plasma and fluid replacement plus anesthetization of the lumbar sympathetic chain on the involved side brought about prompt improvement during the first episode

SUBCONJUNCTIVAL INJECTION OF CORTISONE IN IRITIS

RAPHAEL KOFF, M.D.

ROBERT R. COMMONS, M.D.
RICHARD BUTTON, M.D.
and
PAUL STARR, M.D.
Los Angeles

The purpose of this report is to demonstrate a practical, inexpensive method of utilizing cortisone for treatment of diseases of the eye. The method avoids the undesirable side effects sometimes seen with systemic administration of pituitary adrenocorticotropic hormone (ACTH) or cortisone.

METHOD

The conjunctiva is anesthetized with tetracaine (pontocaine®) hydrochloride. A pledget of 10 per cent cocaine is then placed on the bulbar conjunctiva at the site of the injection, usually at 12:00 o'clock, 5 to 6 mm. from the upper limbus. Cortisone acetate,[1] 0.2 to 0.4 cc. (25 mg. per cubic centimeter), is then injected subconjunctivally with a 23 gage needle. Subsequent injections when indicated are administered at different sites. The procedure is repeated in 48 or 72 hours if necessary.

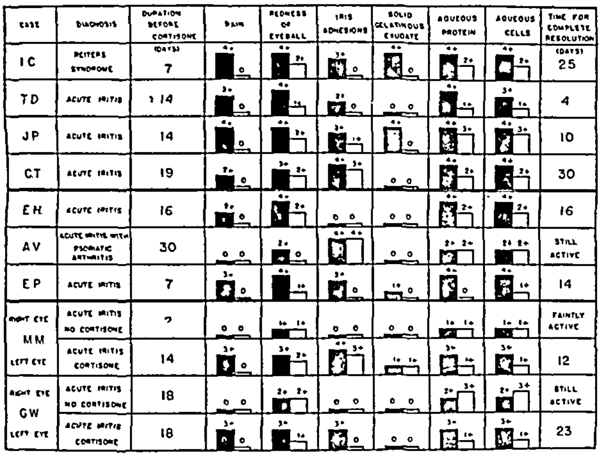

Fig. 1.—Results of subconjunctival administration of cortisone in acute iritis. The shaded portions represent the clinical gradation prior to treatment; the unshaded portions, the clinical gradation 24 hours after the cortisone injection.

RESULTS

Figure 1 shows the results in nine cases of acute or acute recurrent iritis. The shaded portions represent the condition before the cortisone administration. The unshaded portions depict the condition 24 hours later.

Seven of these nine patients had received the usual treatment, including atropine locally, typhoid vaccine injections intravenously, salicylates and heat locally without improvement prior to the local use of cortisone.

In two patients with bilateral iritis (M. M. and G. W.) the worse eye of each was treated with cortisone. The condition of the untreated eye either became worse (G. W.) or remained stationary (M. M.). The treated eye of both patients rapidly improved.

Eight of the nine patients showed remarkable improvement. In these successful cases there was a similar pattern: First, pain disappeared within four to 12 hours; second, hyperemia of the eyeball decreased markedy; third, gelatinous exudate, when present, melted away in 24 hours; fourth, newly formed iris adhesions previously unresponsive to atropine were broken away, and the pupil became widely dilated. Old organized synechiae were unaffected (figs. 2 and 3).

Only two, or at most three, injections were necessary to convert a previously refractory inflammation into a subsiding process. Atropine was used locally during resolution.

Cortisone was used subconjunctivally in six cases of chronic granulomatous uveitis. The patients had previously been treated with pituitary adrenocorticotropic hormone[2] in adequate dosage for six to 10 weeks. Three patients who did not respond to adrenocorticotropic hormone did not respond to cortisone injected locally. Three patients who responded to adrenocorticotropic hormone had recrudescence of inflammation within a few days after cessation of its administration. Subconjunctival injections of cortisone arrested the inflammation in the hormone-responsive group. Repeated injections of cortisone have been necessary at one to three week intervals to maintain remission.

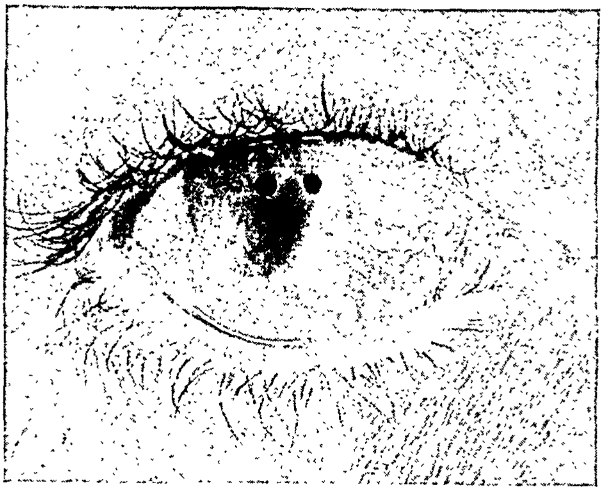

Fig. 2.—Acute iritis after one week of treatment with atropine and intravenous injections of typhoid vaccine. Note the intense hyperemia and the miotic pupil adherent to lens.

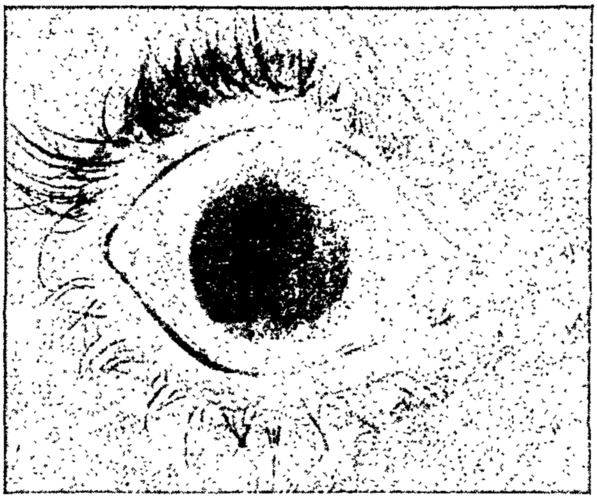

Fig. 3.—Same eye 24 hours after the first subconjunctival cortisone injection. Note the absence of hyperemia, the widely dilated pupil and the disappearance of iris adhesions.

COMMENT

The deposit of cortisone under the conjunctiva disappears gradually without leaving a visible trace. There have been no local harmful sequelae, either immediate or late, from these injections. The procedure is practically painless when done according to the technic described.

It is to be emphasized that cortisone injected subconjunctivally does not cure the iritis. However it does change the process

---

Dr. William Endres aided us by making available the cases on his service at the Los Angeles County Hospital.

From the School of Medicine, University of Southern California and from the Los Angeles County General Hospital.

[1] The preparation used was cortone,® supplied by Merck & Company, Inc. (Dr. J. M. Carlisle, Medical Director).

[2] The pituitary adrenocorticotropic hormone was supplied by the United Laboratories, Pasadena, Calif., through arrangements with Mr. Richard Bruner.

from one of an acute increasing inflammation to a low grade, easily controlled, subsiding one. Atropine or scopolamine mydriasis was used during convalescence.

Subconjunctival injection of cortisone has an effect similar to but better than successful intravenous typhoid vaccine therapy. It has these advantages over the latter: (1) The effect is much more pronounced; (2) the patient is ambulatory, not prostrated by chills and fever, and is able to continue working; (3) there are apparently no contraindications; (4) it can be used in the aged and debilitated, and (5) it is successful when typhoid vaccine administered intravenously is ineffective.

It has some advantage over systemic administration of pituitary adrenocorticotropic hormone or cortisone: 1. It is inexpensive and accessible in the small amounts used. 2. It has a repository effect. Repeated injections are not required every eight to 12 hours. The deposit remains under the conjunctiva for several days during which time it seems to remain active. In most of the cases of acute iritis only two, and in none more than three, subconjunctival injections of cortisone were required. 3. There are no systemic side effects. 4. Hospitalization and laboratory follow-up are not required

It is interesting to note that in three cases of chronic uveitis benefited by adrenocorticotropic hormone the subconjunctival injection of cortisone controlled the exacerbations which occurred after withdrawal of the other drug. Those cases of chronic uveitis unaffected by systemic administration of the pituitary hormone were likewise unaffected by local use of cortisone. It is possible that the results of the local injection of cortisone may be an indication as to whether parenteral treatment with pituitary adrenocorticotropic hormone would be effectual.

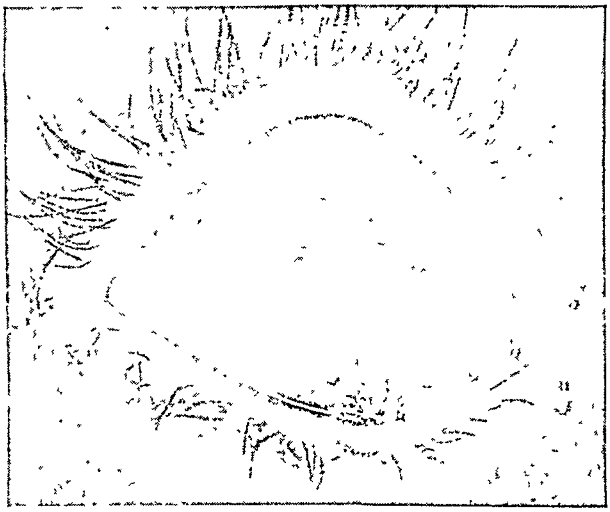

Fig. 4.—Deposit of cortisone subconjunctivally at usual site of injection.

The decrease in the hyperemia of the eyeball that results from subconjunctival injection of cortisone is unusual in that the pallor first appears over and surrounding the cortisone deposit and then spreads outward (fig. 4). This is contrary to the course of events with most other drugs injected under the bulbar conjunctiva, in which the hyperemia remains most intense at the site of the injection.

SUMMARY

A technic is described for the injection of cortisone subconjunctivally.

Nine patients with acute or acute recurrent iritis were treated with subconjunctival administration of cortisone. Eight patients were decidedly improved.

In three patients with chronic uveitis who had benefited by adrenocorticotropic hormone therapy exacerbation developed on cessation of its use, which was controlled by one injection of cortisone with remissions lasting from one to three weeks.

Three cases of chronic granulomatous uveitis unaffected by systemic adrenocorticotropic hormone were likewise unaffected by cortisone injected locally.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following report.

R. T. Stormont, M.D., *Secretary.*

THE STATUS OF BCG VACCINE

One of the most important attempts to develop an immunizing agent against tuberculosis began with the isolation and subsequent attenuation of a strain of bovine tubercle bacillus by Calmette and Guérin of France; this was tried first on calves and heifers in 1908. Oral vaccination of humans with the live attenuated organism (Bacillus Calmette-Guérin, BCG) was then undertaken. BCG vaccine has been widely used abroad, but skepticism has limited its use in this country. The Lubeck disaster of 1930, in which the orally administered vaccine cultured on egg medium produced death in 73 of 252 vaccinated infants, has been shown to have resulted from the accidental inclusion of a virulent strain. Nevertheless, doubt regarding the culture employed in this episode and the reliance placed on domestic control measures have discouraged more extensive employment of BCG vaccine in the United States. The absence of a repetition of this disaster, despite the enormous series of vaccinated infants in Europe, appears to support the contention that the vaccine is not dangerous when prepared from a properly attenuated strain.

The vaccine was administered first orally and later subcutaneously, because the parenteral route produced an allergic (immune?) response in a higher percentage of persons. It is currently administered in the United States by the multiple puncture technic, scarification or intracutaneous injection, to avoid the severer local reactions resulting from subcutaneous injection. For the same reason, a less concentrated preparation of the vaccine is employed for intracutaneous injection than for inoculation by the other two methods.

The instability of the living culture when suspended in a fluid preparation prevents exact control and determination of the number of viable organisms in the currently employed liquid product. The vaccine is adjusted for potency on the basis of moist culture weight; 1 mg. of moist weight growth of the culture should originally give an approximate count of not less than 20,000,000 viable organisms. The intracutaneous preparation contains 1.0 mg. per milliliter, and the multiple puncture-scarification preparation, 15 to 20 mg. per milliliter. *The intradermal dose is presently limited to 0.1 ml. of the less concentrated vaccine.* For several years the liquid vaccine has been prepared in the United States by the following laboratories: Research Foundation, Tice Laboratory, Room 201, 1835 West Harrison Street, Chicago 10; State of New York Department of Health, Division of Laboratories and Research, New Scotland Avenue, Albany 1, N. Y., and The Henry Phipps Institute, Seventh and Lombard Streets, Philadelphia 47. Each of these laboratories distributes the vaccine to those local and state health officials and other authorities who consider the use of the vaccine sufficiently established to warrant its employment in selected groups of tuberculin-negative persons unduly exposed to tuberculous infection.

The Biologics Control Laboratory of the National Institutes of Health has issued a statement of minimum requirements prefaced by the following remarks to indicate the shortcomings of present methods of standardization:

> More data are required on certain essential aspects of the vaccine before these requirements can be entirely satisfactory. *These include* (*a*) the number of viable organisms required in the injected dose, (*b*) the significance of the nonviable organisms present in the vaccine, (*c*) perfection of a fully adequate method of preparing the vaccine in the dried form and (*d*) establishment of a safe storage period and a proper dating period.

The minimum requirements of the federal agency include specifications providing for a 10 day limit of viability for liquid vaccine and up to six months for dried vaccine. Commercial distribution of the vaccine by regular manufacturers of biologic products has not been feasible because of the relatively short life of the micro-organism in the currently used liquid preparations. The time required to complete potency tests on the liquid vaccine is longer than the 10 day limit for use after harvesting the culture. Furthermore, the ratio of viable to nonviable bacteria is subject to considerable variation after preparation of the liquid vaccine, so that it is not possible to estimate accurately the number of live organisms administered in the liquid vaccine at different intervals within the dating period. The nonviable bacilli are considered to have some immunizing effect, but the significance of this in comparison with the effect derived from viable organisms has been difficult to determine. Thus far, however, induction of allergy to tuberculin by means of a vaccine containing only killed bacilli has been less satisfactory than when attenuated live organisms were used. The successful preparation of a dried vaccine is likely to be a step in overcoming the problems of adequate standardization and wide distribution of the finished product. With the advent of stable dried preparations it may be easier to evaluate the ultimate efficacy of BCG in stimulating a positive tuberculin reaction.

The use of the tuberculin test is considered an essential preliminary to vaccination except in newborn infants. Only nonreactors should be given the vaccine Those are considered susceptible who do not react to either 0.0002 mg. of purified protein derivative (PPD) or 0.1 mg of old tuberculin (OT). Vaccination is performed within two weeks of the test in persons with negative reaction, and all vaccinated persons are retested with either form of tuberculin (preferably the same form and dose used prior to vaccination) after eight to 10 weeks. Follow-up testing of newborn infants may require use of a larger dose, 0.002 mg. of purified protein derivative or 1.0 mg. of old tuberculin Revaccination is performed on those who remain tuberculin negative on retesting, and annual follow-up with retesting and chest roentgenogram of both initial reactors and nonreactors is advisable..

Encouragement for wider use of BCG vaccine stems primarily from statistical studies, made in this country and Europe, which tend to substantiate claims that the morbidity and mortality rate has been reduced among certain exposed segments of the population. Although the validity of certain previous studies is questioned by some authorities, it appears that, where the disease is prevalent through the inadequacy or impossibility of exercising proper control measures, the use of the vaccine has been shown to be justified. The following quoted statement on BCG vaccine, issued by the American Trudeau Society, Medical Section of the National Tuberculosis Association, summarizes the present opinion of that organization regarding the place of BCG vaccine in the control of tuberculosis:

> The members of the Society and other physicians in the United States have been interested for many years in the active immunization against tuberculosis with BCG. The expansion of public health activities in the field of tuberculosis control by official and voluntary agencies and the acquisition of new knowledge concerning immunity in tuberculosis have prompted the American Trudeau Society to make the following observations and recommendations:
>
> I. BCG vaccine prepared under acceptable conditions, and administered by approved technics to persons negative to tuberculin, can be considered harmless.
>
> II. The degree of protection recorded following vaccination is by no means complete, nor is the duration of induced relative immunity permanent or predictable The need for further basic research on the problem of artificial immunization against tuberculosis is recognized and is to be emphasized Studies should be directed toward (*a*) improvement of the *immunizing* agent, (*b*) development of criteria for vaccination and revaccination, (*c*) more accurate determination of which groups in the general population should be vaccinated (several well controlled studies are under way at the present time), (*d*) promotion of carefully controlled investigative programs, which, as a rule, will be carried out best under auspices of official agencies such as the U. S Public Health Service, state and municipal health departments, and other especially qualified groups, and (*e*) devising of adequate record systems for management of statistical problems involved in recording and following large numbers of vaccinated people.
>
> III. On the basis of studies reported in the literature, an appreciable reduction in the incidence of clinical tuberculosis may be anticipated when certain groups of people who are likely to develop tuberculosis because of unusual exposure, inferior resistance, or both, are vaccinated (*a*) In the light of present knowledge, vaccination of the following more vulnerable groups is recommended, provided they do not react to adequate tuberculin tests: (1) doctors, medical students, and nurses who are exposed to tuberculosis, (2) all hospital and laboratory personnel whose work exposes them to contact with the bacillus of tuberculosis, (3) individuals who are unavoidably exposed to infectious tuberculosis in the home, (4) patients and employees in mental hospitals, prisons, and other custodial institutions in whom the incidence of tuberculosis is known to be high and (5) children and certain adults considered to have inferior resistance and living in communities in which the tuberculosis mortality rate is unusually high
>
> IV. It is recommended that efforts be continued to perfect and to meet *in practice suitable standards for the production* of BCG vaccine and that, when practicable, commercial firms be licensed under the National Institutes of Health to produce this vaccine
>
> V. The Society believes that since BCG vaccination affords only incomplete rather than absolute protection, the most effective methods of controlling tuberculosis in the general population are (*a*) further improvement of living conditions and the general health, (*b*) reduction of tuberculous infection, which can be accomplished *by modern public health methods and the unremitting* search among presumably healthy individuals for patients with infectious tuberculosis, (*c*) prompt and adequate medical and surgical treatment of patients with active disease, (*d*) segregation and custodial care of those not amenable to accepted forms of therapy and (*e*) adequate rehabilitation.
>
> VI. It is to be emphasized that BCG vaccination must not be regarded as a substitute for approved hygienic measures or for public health practices designed to prevent or minimize tuberculous infection and disease Vaccination should be regarded as only one of many procedures to be used in tuberculosis control.
>
> VII. Expansion of modern diagnostic, therapeutic and rehabilitation facilities is required at this time to make full use of these new methods which can accomplish further dramatic reduction of tuberculosis mortality and morbidity rates in the United States

In view of the difficulties in standardization of the vaccine and the controversial nature of previously published reports, the Council also sought the opinions of various other authorities. Most of them agree that, as now prepared and used, the vaccine is relatively safe. Some skepticism has been expressed regarding its complete safety for general use in infants.

Opinion is varied as to its efficacy or place among other methods for the control of the disease. It is obvious that undue reliance must not be placed on the vaccine as a protective measure at the expense of established measures of control. Most authorities agree that the vaccine is useful only as a partial immunizing agent. Because positive reaction to tuberculin following vaccination merely indicates sensitization rather than real immunity, some clinicians question the reliability of the Mantoux test as a means of determining either the need for BCG vaccine or its effectiveness as a prophylactic agent. Furthermore, there is considerable variation in the care exercised in performance and interpretation of the intradermal tuberculin test. Conversion of nonreactors to reactors through large scale use of the vaccine may alter the significance or destroy the value of the tuberculin test as a diagnostic screening method for detecting acquired exposures in community control programs.

Most authorities agree with the statement of the American Trudeau Society that BCG vaccination should be performed only among selected groups of nonreactors who are most likely to be exposed to infection Physicians in each locality must thus determine whether its use is warranted in accordance with present restrictions and without jeopardy to established control methods. At present, the control of tuberculosis by BCG vaccination should still be considered experimental. There is no scientific support for the contention that BCG vaccination should be extended to all persons with the same assurance that can be recommended for smallpox vaccine and other well established immunizing agents. Whatever protection may be provided by BCG vaccine, there is little doubt that it does not stimulate the development of the same degree of active immunity as is obtained with characteristic immune response produced by derivatives of the causative agents in certain other communicable diseases.

The Council desires to encourage the search for an effective immunizing agent against tuberculosis Improvements in BCG vaccine and further controlled studies which will permit definite conclusions regarding the value and limitations of this agent are necessary. At present the general use of BCG vaccine for all infants, children and tuberculin-negative persons in this country does not appear to be warranted and should not be encouraged.

BRONCHOSCOPY IN PULMONARY TUBERCULOSIS

Bronchoscopy should always be determined by the lung specialist, and only on rare occasions by the bronchoscopic expert, according to Nils Froste[1] of the Central Sanatorium in Sandtrask. On the other hand, he may determine contraindications or reject bronchoscopy because nothing can be gained from it in certain cases. An effort was made by Froste to observe whether bronchoscopy is a diagnostic and therapeutic aid in pulmonary tuberculosis and whether the method presents too great a detriment or hazard to the patient. This is particularly pertinent when paraaminosalicylic acid and streptomycin are used in the treatment of bronchial conditions.

As a result of over one thousand bronchoscopic examinations on 420 patients, Froste notes debilitation and extensive laryngeal tuberculosis as contraindications. As a rule, perforations can be recognized early. Later, ulcerations make them indistinguishable from mucous membrane tuberculosis. In 88 cases bronchoscopic changes were not observed; in 52 cases nonspecific changes were noted that, in a number of cases, caused stenosis. The local treatment of tuberculosis of the mucous membrane has lost importance since the advent of streptomycin and paraaminosalicylic acid. Cauterization with 10 to 50 per cent silver nitrate solutions and galvanocautery were used for treatment, with greater bronchostenosis from the cautery. In patients suspected of having bronchostenosis, the clinical symptoms to a certain degree proved unreliable or the stenosis was beyond range of vision. In about half the cases with suspected valve mechanism, stenosis was probably the cause. The only form of treatment was removal of granulations causing the valve, but no suitable case was encountered. Dilation gave no lasting results, nor were results of aspiration treatment encouraging. For atelectasis, the cause was shown in about 45 per cent of those examined, and about half of these had tuberculosis of the bronchial mucous membrane with or without bronchostenosis. Silver nitrate, cautery and aspiration were used; the atelectasis disappeared in four of 23 treated with silver nitrate, while the atelectasis disappeared only temporarily after aspiration. For hemorrhage of unknown origin, bronchoscopic examination did not reveal the cause. Occlusion treatment with galvanocautery revealed cavity collapse and bacillary freedom in about one fourth, while the remainder were unimproved. Aspiration treatment was used in pressure cavities, in nonpressure large cavities and for stagnant secretions. In six cases with pressure cavity, collapse did not occur; results were equally disappointing with larger-sized nonpressure cavities. Bronchoscopy can be important in identification of the side-producing bacilli and in the procurement of secretion for examination. In differential diagnosis, cases of bronchial cancer and Schaumann's lymphogranuloma benignum were revealed. In some cases bronchoscopy was performed before pneumothorax, and thus pneumothorax was omitted in a few cases with bronchostenosis. Atelectases occurred in about a third of the cases of pneumothorax without previous bronchoscopy. In pulmonectomy and lobectomy, bronchoscopic examination is valuable for ascertainment of a healthy bronchial stump. One fourth of the cases with positive tuberculous findings showed progression after biopsy. Fewer complications arose in 10 per cent of the bronchoscopic examinations, mainly in cases of bronchial mucous membrane tuberculosis and bronchostenoses. Bronchoscopy gives the clinician much previous information from a diagnostic and therapeutic viewpoint. As far as complications are concerned, anesthesia constitutes the greatest danger, but, with knowledge of the proper methods of treatment, such fatalities can be avoided.

ACTIVITIES OF STATE MEDICAL SOCIETIES IN CHRONIC ILLNESS PLANNING

State and local medical societies are taking an active part in launching chronic illness activities throughout the country, according to a recent survey by the Commission on Chronic Illness. Statewide studies of the chronic illness problem have been made with medical society cooperation in California, Connecticut, Illinois, Maryland and New York. The New Jersey Medical Society is advising the Governor's Committee on Chronic Illness in that state, and in Indiana a recently appointed Governor's Committee on which the Indiana Medical Association is represented is now getting underway. Three state societies, North Carolina, Minnesota and Ohio, recently appointed chronic illness committees. In Wisconsin the medical society has been working actively to develop chronic illness legislation for some time. Replies to the commission's questionnaire from the New Mexico, Colorado, Oklahoma and Rhode Island societies indicate considerable interest in establishment of chronic illness committees in those states.

Although chronic illness affects all age groups, the steadily increasing proportion of the aged in our population gives activities in the field of geriatrics much significance in combating the total chronic illness problem, and some of the state societies are approaching the problems through special committees on the aging. In Michigan the geriatrics committee of the state medical society appointed a Subcommittee on Problems of Caring for the Aged, and the Washington State Medical Association reports that one of its committees has made a survey of the aged group in the state. Committees on care of the aged have been established by some of the county societies in Wyoming. The specific chronic diseases have for many years been under consideration by committees of the state societies. Through this single disease approach medical societies in many states have stimulated programs concerned with alcoholism, arthritis, cancer, diabetes, rheumatic fever, conservation of vision, prevention of deafness, industrial health, nutrition and physical and vocational rehabilitation.

---

[1] Froste, N.: Bronchoscopy in Pulmonary Tuberculosis: A Clinical Study of 1,001 Cases of Bronchoscopic Examinations, Acta tuberc. Scandinav., 1950, supp. 23, pp. 7-119.

The establishment by state medical societies of committees on chronic illness seems to be an indication of a growing recognition of the common medical, social and economic factors of chronic disease and the need for a unified approach to the whole problem. A reply from one state medical society to the commission's questionnaire succinctly expresses this viewpoint: "While each chronic disease or group of diseases is a specialty . . . of some physicians, it doesn't seem advisable to have a committee for each disease, as we have started to do. The solution may be to have a Committee on Chronic Illness with subcommittees for the various diseases."

WHY MEDICAL ECONOMICS?

Recent papers by Dr. R. B. Robins, Vice President, American Medical Association, have provoked considerable comment on the questions What is medical economics? What does it mean? The answers are important to the general population and particularly to the medical profession. They are important because they are intimately and directly related to health, happiness and freedom.

Increasingly, medical economics is a topic of everyday conversation. People everywhere are now asking about the cost of medical care, the numbers of health personnel, ways to make medical care insurable and means of assuring every American the medical care he needs. As never before, medical economics is in the spotlight of public and medical discussion. Why is there this sudden interest? Is it due to a grave health crisis in this country? Has the cost of medical care suddenly shot upward? Is the prevailing pattern of medical care no longer meeting the needs of most Americans?

Technological changes in medical treatment have come so fast in the past 10 years that they now may seem overwhelming and, in some respects, confusing to those who attempt to interpret their significance. Some of the new wonder drugs have greatly reduced the cost of treating many diseases, such as mastoid infection and pneumonia, but increasing knowledge of how to treat the sick and improvements in diagnostic technics have introduced some expensive and complicated procedures which increase the dollar cost of medical care to some patients and seem to produce greater variability in costs than formerly.

The dollar cost of medical care has risen during the postwar inflationary period. Medical care prices, however, have not risen nearly as fast as the cost of living. Moreover, the entire amount paid for medical care during the past 20 years has fluctuated narrowly around 4 per cent of total consumer expenditures for all goods and services. A family, however, may well look with alarm at the prospect of severe illness, which can mean a heavy drain on the family purse during these days of cheap money. The costs of medical care in any given year for particular families may exceed the normal of 4 per cent of total family purchases, although, on the other hand, the costs in other years may be negligible. The important thing is for the average family to view with such alarm the prospect of severe illness that it seeks a way to offset the temporary financial hardship that may occur when serious illness strikes. The most widely discussed and practical way is voluntary insurance. Americans have traditionally resorted to insurance when faced with risks which can be predicted only for a group. Today the American family can largely solve its own problem of medical economics by buying voluntary health insurance. Inflation has made it more necessary for the family to use insurance to normalize the costs of medical care and to buy, for example, more fire and life insurance.

But it is not the dollar cost alone which has brought medical economics to the forefront of public attention. Medical progress has transformed the life of the average man. Even 20 years ago there were serious problems of maternal and infant mortality in many sections of this country. Today the low maternal and infant mortality rates and the high life expectancy at every age in the best state and the worst are remarkably close together. The degree to which medical care is available to the general population and the favorable circumstances which have provided better food, housing and sanitation as our standard of living has improved have produced an ever longer life for more and more people. The number of physicians per 100,000 population in this country is the highest of any nation except Palestine, where many of the refugee physicians are not in practice.

Medical economics has come to the forefront in recent years because the vexatious problems of health of a decade or two ago have largely been solved, although others appear to take their place in the unending quest for better health and longer life. Ironically, the increase in the number of persons dying from heart disease and cancer is a measure of past medical progress. Health progress has enabled an increasing number of persons to live on into the higher ages of life when security becomes a major objective. And the voting strength of these older people who seek security—some would sacrifice basic freedoms to have their future guaranteed by law—is growing. Health progress has given them increased voting power.

With an aging population, medical economics becomes a part of a much larger problem of the need to change our social concepts to fit a new world. People made conscious of the magnificent achievements of American medicine look for more and more. And more and more they will have. Yet it is the disturbing premise of the practice of medicine that the doctor cannot win. He can change only the age and cause of death; he cannot prevent the eventual occurrence of death. Our task today is to redefine the problems of medical economics. An older population needs income—not medical care alone. Our working population needs to learn about voluntary insurance—not be forced to purchase overpriced compulsory insurance. And we must remember that, while medical care can never seem adequate to the family of a dying person, it can go on to provide more and better years for more and more of the American people.

Medical progress has come so fast that it seems to many people to be automatic and effortless. Yet the effort required in an inflationary period to earn the money to pay for the medical care resulting from this progress, as well as for all other goods and services, continues to be very real to the consumer. In summary, medical progress itself and cheap money are the principal reasons for the emergence of medical economics as a major aspect of the practice of medicine.

ACTUARIAL PROGRESS BY BLUE CROSS AND BLUE SHIELD

Voluntary health insurance plans have grown during the past two decades from humble beginnings. While the growth has been progressively forward, at times it has been erratic. In some instances plans were started by persons who, while well meaning, knew little about insurance. In most instances, however, expert advice has guided the development of the various plans and, as experience was gained, more effective organization, planning and coverage were provided. In various ways such improvement is obtained. For example, the recent publication of an actuarial and statistical manual by the Blue Cross Commission and the Blue Shield Commission, replete with punch card forms and coding instructions for the many types of illnesses which result in claims, marks a significant step forward. Some of the older plans, however, have well established statistical procedures. Although this manual has not yet been put into operation by all Blue Cross and Blue Shield plans, its publication signifies clearly to the American people that those responsible for these plans are determined to develop actuarial and statistical analyses of their operations so that they may attain or even exceed the level of knowledge which many of the older insurance companies have already developed regarding their own operations.

The Blue Cross Commission and the Blue Shield Commission urge their member plans to use these new procedures, and it is expected that by the end of 1951 most plans will be keeping these uniform actuarial and statistical records. When all plans collect and record their basic data regarding income, membership exposure and utilization according to the procedures set forth in this new manual, the boards of directors of these plans should be in a position to determine future planning with even more confidence. The actuarial and statistical committee of the Blue Cross Commission and the Blue Shield Commission, and particularly their actuarial staff, are to be congratulated for taking this progressive step. It will help the plans to meet the ever changing needs of the American people for health insurance.

THE USE OF EXPERIENCE

In an address to the Hunterian Society, Sir Heneage Ogilvie,[1] distinguished British surgeon and editor of *The Practitioner,* emphasizes the importance of experience, as a prerequisite for judgment, in the field of medicine. Experience, as Sir Heneage points out, consists of impressions received by the five senses, but many fail to gain wisdom from these impressions, for "experience can be made useful only by certain qualities of the mind, some given by inheritance, some by parental example, some by the influence of teachers or writers."

Sir Heneage Ogilvie considers that inability to profit by experience may be attributed to three factors. First, through a failure to acquire the habit of thought, a person may be unable to classify his experiences and thus to step from "experience to experiment." Second, through overclassification, he may fail to grasp the significance of a new experience in his effort to place it under an existing category. Third, specialization of knowledge may blind him to his own areas of ignorance, leading him to forget that "the highest wisdom is the realization that no man can know everything."

The problem then arises as to how to utilize our experiences to best advantage. Sir Heneage suggests that each new experience should be welcomed, scrutinized carefully and with an open mind and then allotted "to one of the trays on our mental desk: 'action,' 'pending' or 'finished.' " In so doing, however, individuality must be preserved, and knowledge received from books and teachers should be looked on as "a help, but not as a directive." This mental file of experiences requires constant rearrangement, for earlier experiences must continually be reexamined and reclassified on the basis of more recently acquired knowledge. Thus conclusions should never be considered final but "merely as the best we have been able to do with the material we have encountered so far."

---

[1] Heneage, O.: The Use of Experience, Brit. M. J. **2:** 663 (Sept. 24) 1949.

Experience properly used provides a standard whereby fresh experiences can be judged. Thus experience permits a physician to sum up quickly his patients as human beings, to recognize instantly danger signs in common complaints, to appreciate the limitations of a given technic and to tackle new problems with assurance. It is from experience that wisdom is gained, but "let us remember," cautions Sir Heneage, "that experience is never finished and wisdom is never complete."

MORBIDITY A PROBLEM IN TUBERCULOSIS

The British tuberculosis publication *Tubercle* calls attention to a condition that has confused medical interpretation for centuries.[1] For a long time *Tubercle* has been interested in the paradox of the decreasing tuberculosis death rate in England and Wales and the apparent increase in morbidity, and three years ago it produced graphs showing that the United States and Canada were having a similar experience. At that time the opinion was expressed that the increase in notifications represented an improvement in ascertainment rather than a true increase in morbidity, and this view is still held today. The threshold of notification seems to be at a different level for each doctor. Some report symptomless primary lesions in children; others do not; some even notify at the time of conversion of the tuberculin test; some report symptomless quiescent lesions discovered at mass radiography, which is most likely when the examinee is in the armed forces. Pleural effusions often escape notification as do tuberculous eyes or skin. A zealous physician, seeking a record in his district, gives the superficial impression that a serious epidemic has been sweeping his district since his arrival. New men and older men of modified opinions have meant an awareness of tuberculosis, and reported patients now qualify for more benefits than formerly. Consequently more patients are reported and the apparent morbidity increases. With the increase in the age at which first infection occurs, one must expect an increase in morbidity; primary infection is more serious in postpuberty, about which *Tubercle* expresses uneasiness and states that if there is a true increase in morbidity in young persons, then by all previous rules there should be a similar increase in mortality. It is doubted that this is occurring, but time will tell. Thus what appears to be a simple problem in tuberculosis is not necessarily simple when examined statistically.

---

COXSACKIE POLIOMYELITIS INFECTION

In the 1949 epidemic in Easton, Pa., fecal samples were collected from 48 consecutive patients admitted to the hospital for poliomyelitis. From 15 of these patients Melnick and Kaplan[1] of Yale University isolated both poliomyelitis and Coxsackie viruses. The question arose as to whether this meant a dual infection or merely a passive transfer of one virus through the alimentary tract. To answer this question they obtained serums from two typical paralytic patients on the third and fourth day of the disease and about 30 days later. *An 18,000 r.p.m. supernate of a 1:10 dilution of* the patient's stool was mixed with an equal volume of his own diluted serum. After standing for two hours at room temperature, each serum-virus mixture was inoculated into three monkeys in a test for poliomyelitis virus and into at least eight newborn mice in a test for Coxsackie ("C") virus.

In one patient the highest serum dilution which neutralized "C" virus on the third day of the disease was 1:10, increasing to a titer of 1:90 by the thirty-second day. A dilution of 1:10 of the same serum also neutralized completely the patient's poliomyelitis virus on the third day, increasing to a titer of 1:270 by the thirty-second day. Similar titers were obtained with the second patient.

Melnick concludes from this evidence that they were dealing with an infection with the two viruses. It is conceivable that the clinical symptoms might have been milder if the superimposed "C" virus had not been present. "C" virus may conceivably be one factor which turns a nonparalytic into a paralytic case.

POSTGRADUATE CONTINUATION COURSES FOR PHYSICIANS

The semiannual listing of postgraduate continuation courses for physicians, covering the period Jan. 1 to July 15, 1951, appears elsewhere in this issue. These data, prepared by the Council on Medical Education and Hospitals, include about 750 courses varying in length from a few days to several months and are available both for the physician in general practice and the specialist. Courses are being given in 29 states. The subjects covered embrace 45 major areas in the field of medicine. The increasing number of courses available for continuation study for the general practitioner is of particular interest. In keeping with the present world situation, courses are being presented in civilian defense and the nuclear sciences. The Council endeavors to make this listing as complete as possible. Institutions and organizations whose courses are not included in the present list are invited to furnish the Council with details pertaining to the opportunities that they have developed for continuation study by physicians.

WASHINGTON NEWS

(From the Washington Office of the American Medical Association)

Civil Defense Administration

It is now clear that the federal government is going to move into the civil defense situation, and without delay. This will mean, among other things, that medical preparations will be stimulated all down the line and that a start can be made on building up regional stockpiles of medical supplies. Since last September 19 a bill to create a Federal Civil Defense Administration has been before the Senate Armed Services Committee (S. 4162, which was reviewed at some length in this space on September 30). Last week several similar bills, but giving the federal government greater power, were introduced in both House and Senate. But Mr. Truman did not wait for Congress to act. Instead he used his executive powers to set up a Civil Defense Administration, which will function as an independent agency while Congress debates the bills. Civil defense activities of the National Security Resources Board, including its medical section, were moved to the new agency.

Mr. Truman did not immediately make public the executive order effecting the changes, so it is impossible to say just how much authority has been delegated to the new agency and its director, Millard F. Caldwell Jr., former Florida governor and former congressman. However, there is no question that Congress shortly will vote Mr. Caldwell all the powers needed to carry out his assignment. Under all the bills, the Civil Defense Administration would knit together regional and local civil defense organizations and authorize the federal government to step into the picture if state or community groups fail to meet their responsibilities in case of disaster.

Demands for Medical Manpower

At this writing it is impossible to say how many more physicians will be needed for the expanded military mobilization. Since July 1 the armed forces have increased from about 1,500,000 to just under 2,200,000. Up to the time of the new Korean crisis, military planners were aiming at a total force of 2,800,000 by July 1, 1951. It was expected that the accompanying medical requirements would be met largely by physicians classified 1-A and 1-A-O in the draft and reserves of similar status. However, plans now call for reaching the 2,800,000 mark several months earlier. When that time comes, the services undoubtedly will have to start calling in doctors now in deferred draft classifications, as well as reserves with World War II experience. When Mr. Truman made his request for $18,000,000,000 in supplementary defense funds, he did not specify a new manpower total but used these words to make it plain that one would have to be set: "We now face the necessity of having to raise our sights both in terms of manpower and in terms of production."

Last fall the services asked for a manpower ceiling of 3,500,000, but Congress refused to go that high. If, in view of the more critical situation, that total should now be decided on, several thousand more physicians would have to be provided—and most of them would be men who now are not expecting to be called.

The Doctor Draft

The National Advisory Committee to the Selective Service System, set up to assist in the doctor draft, has scheduled a conference of state advisory committee representatives for January. The National Committee will meet on January 11 and the state members on January 11 and 12. The plan is to have the chairman and two other members of each state committee present, representing physicians, dentists and the state health officers. Current problems will be discussed, particularly difficulties in effecting deferment of essential interns and residents.

In a message to state committee chairmen, Dr. Howard A. Rusk, chairman of the national committee, urged all advisory committees to support "unequivocally" requests for deferment of men who have not finished their first year of internship. At present, internship is interpreted as postgraduate education, but the requirement of one year's internship for military medical service, and generally for civilian practice, suggests that local boards would be willing to defer men in this status.

Dr. Rusk also advised state chairmen that hospital training beyond one year is to be regarded as a residency, not an internship, even though the internship may be of two years' duration. Meanwhile, National Selective Service Headquarters has requested local boards to "reopen and consider anew" the case of any special registrant at any time prior to issuance of an induction order "if the state or local advisory committee submits evidence and requests deferment."

Other important developments in the doctor draft:

1. The fact that a man has been placed in 1-A or 1-A-O does *not necessarily mean he will be inducted immediately.* A number of Selective Service boards so designated registrants in order to have them complete their physical examinations and be ready for induction should the advisory committees decide them available. If evidence suggests such men should be deferred, state and local advisory committees are urged to take action.

2. There are no blanket policies for interns, residents and teaching and research personnel; advisory committees consider each case individually.

3. In determining essentiality, advisory committees are giving particular attention to teaching programs and small community hospitals whose one year residents are necessary for the continuation of adequate services. Dr. Rusk said that inquiries indicated shortages particularly in psychiatry, neurology, public health, radiology, anesthesiology, pathology, physical medicine and rehabilitation, tuberculosis and research.

4. Preliminary estimates based on samplings indicate that, of the 14,000 physicians registered in priorities 1 and 2 of the draft, about 7,400 are currently in residency training and 1,800 in internships. This means that well over half of the potential supply for the first call are located in hospitals, where their immediate removal would in many cases create community problems.

Military Notes

The Air Force still is accepting reserve commission applications from registrants in draft priorities 2, 3 and 4, but is no longer accepting applications from those in priority 1. . . . The Army is calling up a number of Medical Service Corps reserves through the rank of captain on mandatory orders. . . . The Army wants 3,000 volunteer nurses and 250 women medical specialists, to meet requirements through June 30, 1951. The Army already has called 650 nurse reserves and 145 medical specialists on mandatory orders, and 477 nurses and 17 specialists have volunteered. Incidentally, the Army has reached the point where its nurse reserve rolls are deceptive; 2,200 of them are now on duty at Veterans Administration hospitals, and other hundreds are in similar essential positions or are ineligible for recall because they have children under 18 years of age.

Committee on Chemicals in Foods

The House Select Committee on Chemicals in Foods, resuming hearings in Washington, cited an article in The Journal of The American Medical Association as evidence that the public requires more protection. The item was a note of caution, "Pesticides: A Statement Concerning Needed Information" (**142**:259 [Jan. 28] 1950). The committee counsel read a digest of the article to Lea F. Hitchner, executive secretary of the Agricultural Chemicals Association (a group of producers) and asked whether he disagreed. Mr. Hitchner said he did disagree and that he thought the Council on Foods and Nutrition, which authorized the statement, might believe differently now. He said that subsequently the Council had been informed of the tremendous amount of research work being done on these chemicals. However, in reply to another question by counsel, he said he had not asked the American Medical Association Council for a supplementary statement.

Prior to this exchange, Mr. Hitchner had said that his association believed that what was needed was not a new law to protect the public but better enforcement of the present law. He said that 20 of the 30 major producers are spending about $3,000,000 a year in research.

Another witness, Dr. Arnold J. Lehman, director of the Division of Pharmacology, Food and Drug Administration, discussed results of investigations on toxicity of several fungicides, pesticides and other substances. He said FDA had worked for two and a half years on a study of dulcin, an artificial sweetening agent about 200 times as sweet as saccharin. According to Dr. Lehman, the investigation made it quite evident that: "dulcin is a poison and should not appear in food." He said that producers of dulcin preparations and a similar product, identified as P-4000, had complied with requests that they not be used in food. These substances, he said, were used on rats, giving the animals proportionately the same amount of the drugs humans would receive. Dr. Lehman said the substances were found to "inhibit growth, to have adverse effects on blood and to produce liver tumors." He noted that one trade name for dulcin is sucrol but emphasized that this is not to be confused with sucaryl,® which FDA has found to be not harmful.

Dr. Lehman said use of boric acid and borax in food processing or packaging is harmful and that the toxicity level of three other fungicides is "too close to the danger line." These he identified as sodium orthophenyl phenate, diphenyl and dehydroacetic acid.

Dr. Lehman described the insecticide chlordane as "one of the most toxic of insecticides we have to deal with." He said it penetrates the skin readily, is volatile and is "very toxic to liver and kidneys." He said in his opinion it was four or five times as poisonous as dichlorodiphenyltrichloroethane (DDT). Dr. Lehman said that chlordane, as sold in hardware stores for use in spray guns, is too dangerous for home use, although if applied properly is not harmful for certain specific purposes. Dr. Lehman acknowledged that the Food and Drug Administration has no authority in certain fields, even where toxic agents are being distributed.

The committee, under the chairmanship of Representative James J. Delaney (Democrat, New York) is investigating chemicals introduced in foods, chemical pesticides (applied to growing food crops and as chemical preservatives) and chemical fertilizers. One of the suggestions is that the Food and Drug Administration be given the same authority over these substances that it now has over new drugs.

Other witnesses during the week included C. W. Crawford, Deputy Commissioner, Food and Drug Administration; Dr. James B. Allison, director, Bureau of Biological Research, Rutgers University; Dr. John C. Krantz Jr., University of Maryland School of Medicine; Dr. Robert S. Harris, professor of biochemistry of nutrition, Massachusetts Institute of Technology, and representatives of the Department of Agriculture and several cooperative associations. Hearings continue through December 19.

Notes

An issue of *Public Health Reports* (vol. 65, no. 46) is devoted entirely to health resources; a fairly complete picture of civil defense preparations and problems to date but not too much on military aspects . . . Canada and the United States are working on an international agreement for civil defense . . . Acting director of NSRB's Civil Defense Office told the American Welfare Association that there could be no mass evacuation of great cities in case of attack. James J. Wadsworth said, "There will be no retreat from the production lines. There will be no voluntary surrender of a single machine, or a single home, that might help our armed forces to wage war." . . . The American Pharmaceutical Manufacturers' Association has been urged to serve as one of the strong points in civil defense planning, particularly in development of new drugs, establishing storage depots, utilizing laboratories and experimental operating rooms as emergency medical centers and offering its personnel for emergency sick care . . . Of the 100,000 persons helping FSA prepare material for the White House Conference on Children and Youth, held here this week, 15,000 were physicians, teachers, and others dealing with children. Among the physicians to give keynote speeches for the conference were Leonard W. Mayo, and Benjamin M. Spock, both of Rochester, Minn. . . Schools and hospitals wanting to share in United States surplus property now have a clearer picture of what to do. An office of Field Services, Division of Surplus Property Utilization, has been set up in FSA to handle distribution to nonprofit institutions, as authorized by the last Congress. . . . The Navy's Bureau of Medicine and Surgery personnel are sponsoring "Operation Toy" to send gifts to 500 refugee children in Hoffheim, Germany . . . The first of the Navy's three volume series, "Color Atlas of Pathology," has just been published by the J. B. Lippincott Company, Philadelphia. Designed as a usable standard of comparison for study and interpretation of gross and microscopic findings in pathology, this first volume took six years to prepare. Other volumes will be on the market by 1954 . . . The National Technical Task Committee on Industrial Wastes, meeting for two days in Cincinnati, worked on problems of organizing research in water pollution . . . The Gorgas Memorial Institute of Tropical and Preventive Medicine has reelected the following officers: Dr. J. F. Siler, president; Maurice H. Thatcher, vice president; Dr. Walter A. Bloedorn, secretary; Hulbert T. Bisselle, treasurer, and Dr. Donald A. McCormack, assistant treasurer. Mr. Thatcher is also general counsel . . . The Department of Agriculture reports people now are eating just about what they did 40 years ago (per capita), but now greater emphasis is on fruits, vegetables and dairy products. . . . Dr. Thomas Parran, ex-surgeon general and now dean of the Graduate School of Public Health at the University of Pittsburgh, is on President Truman's Advisory Board on International Development, guiding the Point 4 program . . . 32,544 handicapped persons were employed through state employment centers during October, the highest total for any one month ever reported.

ORGANIZATION SECTION

PRESIDENT'S ADDRESS TO THE HOUSE OF DELEGATES

ELMER L. HENDERSON, M.D.
President, American Medical Association

Mr. Speaker, Members of the House of Delegates:

In this general report to you today, I should like to touch briefly on five important subjects, in the following order: financial support of medical education, the position of the American Medical Association with respect to the program of hospital standardization, public health units, the results of the A. M. A. nation-wide advertising program and the significance of the November elections.

FINANCIAL SUPPORT OF MEDICAL EDUCATION

In the last four years the attention of the public and the profession has been called repeatedly to the fact that the postwar period has been a difficult one financially for our medical schools. Inflation, rising costs, reduced income from endowment, and fewer large benefactions, together with increased responsibilities for education, research and community service, have created problems of varying magnitude for the individual schools. At a time when advances in medical science make refinements and improvements in medical education desirable, schools have found it difficult to secure the funds needed for such developments. Furthermore, the present international crisis will in all likelihood create still further problems for the schools.

During the postwar period, increased local support has been of major assistance to many schools in meeting their financial problems. Other schools, particularly the privately endowed schools, have not been so fortunate. For the most part they have not been able to increase their income in proportion to the increases in their costs.

The past year's controversy over the question of federal aid for medical education has made many, both within and without the profession, forget that federal aid is but one segment of the problem of the future financial support of the medical schools. Discussions of this subject have tended to be limited to the narrow issue of whether federal aid is necessary or desirable. Many other sources of financial aid to medical education have been overlooked, and the profession's responsibility to assist actively in gaining additional support for the schools has not been fully recognized. Events of the past year have made it clear that there are those who interpret the American Medical Association's opposition to the bills for federal aid to medical education presently before Congress as indifference to the problems of the medical schools and the needs of the nation for adequate facilities for the training of physicians. We must make it clear that the profession is not indifferent to these problems. Let us face clearly our obligation individually and collectively to provide significant financial assistance to the medical schools and to study other ways by which we can help them meet their problems.

POSITION OF AMERICAN MEDICAL ASSOCIATION WITH RESPECT TO THE PROGRAM OF HOSPITAL STANDARDIZATION

At the San Francisco meeting the Board of Trustees learned that the American College of Surgeons was considering the possibility of conducting its program of hospital standardization in cooperation with other interested organizations. It also was reported that the American Hospital Association had expressed its willingness to assume major responsibility for the future conduct of this program. Subsequently, the House of Delegates of the American Hospital Association passed a resolution authorizing the establishment of a program of hospital standardization to be administered by its Trustees.

Recognizing that any program of hospital standardization would have a direct bearing on the standards of medical practice in hospitals, the Trustees of the American Medical Association, following the San Francisco meeting, began a series of consultations with representatives of the American College of Surgeons, the American Hospital Association and the American College of Physicians in an attempt to clarify the position of these several organizations. As a result of these conferences, I can report that very real progress has been made toward the objective of developing a cooperative program in which the best interests of the public, the hospitals and the profession will be considered.

The most important development has been the decision taken by the American College of Surgeons at its annual meeting this fall to continue its program of hospital standardization in the hope that within the near future a satisfactory plan can be developed for a program in which the American Medical Association, the American Hospital Association and the American College of Physicians also will participate.

Since this decision was reached by the American College of Surgeons, further conferences have been held and further progress has been made. At the last conference two weeks ago, a joint committee of the four organizations named was appointed to draft a basic plan for a cooperative program. The outlook for an agreement within the next six to twelve months on a plan that will be satisfactory to all the interested organizations is very good indeed. I think it important that the House of Delegates should know that after certain initial misunderstandings were cleared away, the representatives of the four organizations have found themselves working together harmoniously in an effort to achieve the common objective of an expanded program which will insure better care of the sick.

PUBLIC HEALTH UNITS

The American Medical Association has long believed that the existence of effective and properly operated public health units is basic to the maintenance and improvement of the health of the people. As early as 1883, a report was made at the annual meeting of the Association covering a survey conducted to ascertain what states and counties had health departments. In the years that have followed, our interest in the subject has remained unabated. Resolutions have been adopted by the House of Delegates urging complete coverage of the nation's population by county, district or regional full time modern health units. Point 6 of our 12 point program gives proper and additional emphasis to the important role that public health departments must continue to fill in our ever expanding and untiring efforts to provide the people with better and better health care. Tremendous progress has already been made; much more needs to be done.

I stress this subject because, unfortunately, action taken by the House of Delegates at the San Francisco meeting in June 1950, with reference to a bill in Congress to authorize federal financial aid for the development of health departments, has led to misunderstanding of the present point of view of American medicine toward the development of such programs.

Did the San Francisco action, in effect, reverse the previous and long-established position of the Association? This is a question that is being asked. In order to remove any doubt about the matter, I should like to suggest that the House give consideration at this session to reviewing the action taken earlier this year for the purpose of clarification. In my judgement, such a review now would be most timely.

Presented at the Fourth Annual Clinical Session, American Medical Association, Cleveland, Dec. 5-8, 1950.

THE A. M. A. ADVERTISING PROGRAM

Since our annual session last June in San Francisco, the main development in the National Education Campaign has been the nation-wide October advertising program, which this House of Delegates approved unanimously at the annual meeting.

I am proud and happy to report that the decision which you made last June has been more than justified by subsequent events. That decision has enabled American medicine to make history in the field of public relations and advertising, as well as in the realm of public affairs and government.

A printed, detailed report on the results of the advertising campaign will be distributed later this week during the clinical session here in Cleveland. Today, however, I do want to give you a brief preview of some of the highlights in our advertising success.

The campaign marked the first time in the history of the United States that a profession, business or industry, under government attack, has been successful in rallying nationwide advertising support from thousands of unrelated groups, companies and individuals.

That unselfish, spontaneous support came from more than 65,000 individuals, firms and associations, with the vast majority located in the small cities and small towns of America. They represented not "big business" but the "grass roots" life of the nation.

Those 65,000 new-won friends of our profession, reaffirming their faith in the American way of life, spent more than $2,000,000 in a two week period, or nearly twice as much as the A. M. A. itself, in support of medical freedom. For that practical assistance and splendid vote of confidence, we should be deeply grateful to the merchants of Main Streets all over America.

Today, as a result of the tremendous impact of our advertising campaign, all the nation knows that American medicine does not stand alone. Thousands of allies have taken public stand beside us.

Major public issues still are resolved by the millions of men and women in this country with a strong sense of independence and responsibility, who think things through and speak their minds. The voice of the men and women who live on Main Street is the compelling voice of America—and it has spoken once again.

THE NOVEMBER ELECTIONS

The people of America also spoke in November, at the polling places of the nation. The election results last month were heartening and reassuring to the medical profession, which has been fighting a nonpartisan fight not only against compulsory health insurance, and against the broad trend toward socialism in America, but for the preservation of this nation's traditional way of life.

Neither the American Medical Association nor the state and county medical societies took part in political activities aimed at the election or defeat of individual candidates. But thousands of doctors and their wives, exercising their rights as individual citizens, did take an active part in election activities in many areas of the country. And let us be thankful that they did.

I have nothing but praise and commendation for all doctors —regardless of their party affiliations—who as American citizens played their rightful role in public affairs, and who fought for their convictions at the polls.

The November elections brought defeat to a number of the most outspoken advocates of compulsory health insurance, and also to a number of candidates who hedged on the issue. The elections also provided a general repudiation of the over-all trend toward state socialism.

I think we can say at this point, in view of the events of the past several months, that the majority of the American people agree with the stand of the medical profession, and that any compulsory health insurance bill in Congress today would go down to defeat by at least a 2 to 1 vote.

But let me close this report with a note of warning. We still have much work to do before all the basic issues confronting us are finally resolved. To relax now, under the delusion that we already have achieved complete victory, would be to invite a renewed attack by the socializers at a later date. We cannot afford to relax either our vigilance or our effort.

SOCIALIZED MEDICINE IS NO BARGAIN

WILLIAM L. HUTCHESON

General President, United Brotherhood of Carpenters & Joiners of America

I am against socialized medicine. So is the organization which I have the honor of heading. At the Twenty-Sixth General Convention of the United Brotherhood of Carpenters and Joiners of America, held in Cincinnati last September, 1,300 delegates, representing better than 54 per cent of the total membership, voted down a resolution to support the national health program. This probably does not jibe with the feelings of a good deal of the rest of the labor movement, because much of the pressure for "free" medical care is coming from labor organizations. But it does reflect my sentiments and the sentiments of our recent convention.

Saving a dollar has never been distasteful to me. In fact, I like to get as much for my money as the next man. That is one of the reasons why I oppose socialized medicine. It is no bargain. It looks cheap the way the backers present it, but when you dig down under the fancy layer of propaganda frosting you find that it can be mighty expensive. The British people have already discovered this fact. The July issue of *International Labour Review,* official publication of the International Labour Office, contains some very interesting data on the operation of the national health service in Britain. I quote a few lines of that report:

"The total (gross) cost of the National Health Service in 1948-1949, the first year of operation, greatly exceeded the original estimate. This was £265,000,000, as against a revised estimate of £368,000,000, with a net cost to the taxpayer of £278,000,000. The revised estimate for the year 1949-1950 was £450,000,000, as against an original estimate of £352,000,000. For 1950-1951 the cost is estimated at £484,000,000; in 1946, when the bill was passed, the service was believed to cost £167,000,000 a year."

In case you don't know what the International Labour Office is, I can best explain its functions by quoting a bit from its preamble:

"The International Labour Office is an association of nations, financed by Governments and democratically controlled by representatives of Governments, of management and of Labour organizations.

"Its purpose is to promote social justice in all countries of the world. To this end it collects facts about labour and social conditions, formulates minimum international standards, and supervises their national application."

The ILO's publication, *International Labour Review,* is published in the United Kingdom. As an international organization, ILO's findings are supposed to be strictly impartial.

Getting back to the report; if I read it correctly, service that was supposed to cost £167,000,000 per year when the plan was set up in 1946 costs £484,000,000 per year, and the end is not yet in sight. By my old-fashioned kind of arithmetic that is an increase of better than 345 per cent, and I am sure my poor old mother, who always made a dime do the work of a quarter, would not consider that kind of proposition any bargain.

I know! I know! The socialists claim that money is of no consequence in the matter of national health; getting the poor the same quality and quantity of medical care as the rich can get under private enterprise is the advertised objective of the

---

Read before a Joint Meeting of the A. M. A. House of Delegates and the Third Annual Conference of the National Education Campaign, Cleveland, Dec. 7, 1950.

National Health Program. That sounds fine, too; but on page 57 of the ILO report, I find the following sentences:

"A survey of the distribution of doctors by boroughs shows that certain wealthier districts (of London) have an average of one doctor for 1,261 patients, while in the inner East End there are 2,472, or twice as many patients, per doctor. For a group of southern boroughs, the average is 2,897."

If that isn't the "one horse and one rabbit" recipe transferred from the meat pie maker's kitchen to the national health program, then I need new reading glasses. I have tried to figure it from all angles, but the answer I always come up with is that the lumbago, shingles and bellyaches of London's South Siders get only half the attention that similar ailments get in the swankier districts. For all the planning that has been done, there is still an uneven distribution of doctors in London. If the backers of the national health program are to achieve their objective of equal health protection for all, the next step must be to tell doctors when and where and how they are to practice. Therein lies my greatest fear of socialization.

Socialization and death have one thing in common; you cannot be either a little bit socialized or a little bit dead. It is whole hog or nothing. After two years of the national health program, London doctors still have preferences as to where they want to practice. By compulsion of one kind or another, somebody is going to have to shoo doctors away from the fancier neighborhoods into the tenement districts or the program will wind up where it started. When the government is given authority to tell one group or one profession where and how its members are to work, no other group or profession can be safe for long.

If the day ever comes to America when Uncle Sam usurps the power to dictate to doctors under a health plan, it will be a sad day for carpenters. Adequate housing is still an unsolved problem in this country, especially for the poor. If it is logical to nationalize the medical profession to get more medical service for the poor, it is equally logical to nationalize the home construction industry to get roofs over the heads of the lower income groups.

I do not know much about doctors, but I know quite a bit about carpenters. They are an independent lot. They want to work where and how they please. The first bureaucrat who told a carpenter he had to work in Little Rock when he wanted to work in Lancaster would be gumming his food for lack of teeth. Carpenters want to be free agents; free to work where they want to; free to negotiate the terms of their wages and working conditions through collective bargaining; yes, even free to leave the industry and try their luck at something else if the spirit moves them.

They will retain these freedoms only so long as all other groups retain them too. Socialization is like a wolf with a tapeworm; once it starts gnawing, it never can stop. Socialized medicine would only be the first bite out of our free enterprise system; it would not be many years before the carpenters would be feeling the teeth of socialization on the seats of their overalls. Anyway you look at it, socialized medicine is no bargain and the carpenters want none of it.

I know that the backers of the national health plan in this country resent the term "socialized medicine." They have all sorts of arguments to "prove" that doctors and patients will remain free as the air under their program. They make a strong case. Perhaps if human nature were less ornery and less avaricious, an idealistic health program might work out all right. But so long as people have preferences, so long as Park Avenue has more appeal than Hell's Kitchen, there will be an uneven distribution of doctors under any plan that does not contain compulsion. And once compulsion enters the picture, the rights and freedoms of all citizens stand in jeopardy. To me, it is as simple as that. For 40 years I have fought communism tooth and toe nail because I do not want anyone pushing me around. I certainly do not want to put my head into a socialization noose voluntarily when the results can be as undesirable as communism.

I have always respected the medical profession for the fine contribution American medicine has made to human welfare. As I watched your battle against regimentation during the past two years, I have added to that respect. The physicians of this country have shown that they are willing to fight for their convictions. I salute you today not only as doctors but as crusading citizens as well. We in the labor movement have our own cross of regimentation to bear. The fight you are making is part of the same war. It is a war against concentration of authority in a few hands in Washington. As a veteran of 40 years in the labor movement, I know what it is to fight for human rights. I am happy to take my stand beside you.

THE SCIENTIFIC EXHIBIT

Atlantic City Session June 11-15, 1951

Each Section of the Scientific Assembly has elected a representative to the Scientific Exhibit for the Atlantic City Session, June 11-15, 1951, as follows:

Section on Internal Medicine, Dr. Wesley W. Spink, University Hospital, Minneapolis 14.

Section on Surgery, General and Abdominal, Dr. Walter G. Maddock, 250 East Superior Street, Chicago.

Section on Obstetrics and Gynecology, Dr. Frederick H. Falls, 1853 West Polk Street, Chicago 12.

Section on Ophthalmology, Exhibit Committee, Dr. Georgiana D. Theobald, 715 Lake Street, Oak Park, Ill., Chairman; Dr. Donald J. Lyle, 601 Union Trust Building, Cincinnati 2, and Dr. Phillips Thygeson, 87 North Sixth Street, San Jose, Calif.

Section on Laryngology, Otology and Rhinology, Dr. Francis W. Davison, Geisinger Memorial Hospital, Danville, Pa.

Section on Pediatrics, Dr. F. Thomas Mitchell, 376 South Bellevue Boulevard, Memphis 4, Tenn.

Section on Experimental Medicine and Therapeutics, Dr. Robert W. Wilkins, Evans Memorial Hospital, 65 East Newton Street, Boston.

Section on Pathology and Physiology, Dr. F. W. Konzelmann, 1711 New York Avenue, Washington 6, D. C.

Section on Nervous and Mental Diseases, Dr. Leon J. Whitsell, 909 Hyde Street, San Francisco 9.

Section on Dermatology and Syphilology, Dr. James R. Webster, 122 South Michigan Avenue, Chicago 3.

Section on Preventive and Industrial Medicine and Public Health, Dr. Paul A. Davis, 1436 Delia Avenue, Akron, Ohio.

Section on Urology, Dr. Roger W. Barnes, 1216 Wilshire Boulevard, Los Angeles.

Section on Orthopedic Surgery, Dr. Robert J. Joplin, 1180 Beacon Street, Boston 46.

Section on Gastro-Enterology and Proctology, Dr. J. P. Nesselrod, 636 Church Street, Evanston, Ill., and Dr. Everett D. Kieffer, The Lahey Clinic, 605 Commonwealth Avenue, Boston.

Section on Radiology. Dr. Richard H. Chamberlain, 3400 Spruce Street, Philadelphia.

Section on Anesthesiology, Dr. Scott M. Smith, 325 Eighth Avenue, Salt Lake City.

Section on General Practice, Dr. Charles E. McArthur, 205 East Seventh Avenue, Olympia, Wash.

Section on Diseases of the Chest, Dr. Edwin R. Levine, 109 North Wabash Avenue, Chicago 2.

Section on Physical Medicine and Rehabilitation, Dr. Arthur L. Watkins, Massachusetts General Hospital, Boston 14.

Application blanks for space in the Scientific Exhibit are now available and may be obtained from the Section representatives or the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10.

GOVERNMENT SERVICES

Army

Consultants to Go Overseas in 1951

Thirty leaders of civilian medicine will go overseas for the Army Medical Service during 1951 as consultants to the surgeons of the Army commands and to bring the latest developments in medical science to Army physicians. The European Command will receive 12 consultants, the Far East Command 12 and the Panama Canal Zone six. The scope of the Army's overseas medical consultant program has been reduced in the past two years, since the graduate professional training program has increased the number of medical specialists in the regular Army. Over 200 regular Army medical officers have now been certified by American specialty boards. Each of the 30 consultants who will be assigned to oversea tours must have been certified by the American Board in his specialty, must have had military experience and must be a recognized teacher.

The schedule for the European Command calls for two-man teams, as follows: February, one pediatrician and one obstetrician; April, one surgeon and one internist; June, one neuropsychiatrist and one orthopedist; August, one internist and one obstetrician; September, one surgeon and one neuropsychiatrist, and November, one internist and one orthopedist.

One specialist wil go to the Far East Command each month beginning in January. The schedule calls for an internal medicine consultant in January, May and September, a neuropsychiatrist in February, June and October, a surgeon in March, July and November and an orthopedist in April, August and December. Internists will be assigned to Panama in February, June and October and surgeons in April, August and December. Each consultant, on his return to the United States, will submit a report and recommendations to the Surgeon General as to administration and treatment, which will also serve as a check on the observations of the Army's own medical specialists.

Decentralize Appointments for Medical Draft Registrants

The inauguration of a decentralized system of reserve officer appointments, which will expedite action on applications made by draft-eligible physicians, dentists and veterinarians, has been announced. Under the new system, the entire processing of reserve commissions will be accomplished in the six Continental Army areas and overseas commands for applicants now enrolled under the current draft call. Commissions will be issued by Army commanders and overseas commanders to applicants who qualify without referral to the Department of the Army. For those subject to induction by Selective Service, the following procedure will be followed:

Initially, the registrant will fill out a questionnaire that will include a statement as to whether he desires to accept a commission. This questionnaire will accompany him to his local induction station when he reports for his physical examination. At that time he will be given another opportunity to indicate his willingness to accept a commission, if he has not previously so indicated. Records will then be forwarded to the appropriate Army headquarters where the qualifications of the registrant will be determined. If the registrant is qualified, the Army commander will send him a letter of appointment in an appropriate grade in the Medical, Dental or Veterinary Corps Reserve, with instructions to complete an oath of office within 72 hours and notify his Selective Service Board of his commissioned status. Physicians and dentists accepting commissions under these circumstances will receive the special $100 authorized pay for volunteers.

Awards and Commendations

CAPT. WARREN H. BRUNE

The Silver Star was recently awarded to Capt. Warren H. Brune, formerly of St. Louis, "for gallantry in action against the enemy at Kumchon, Korea." On August 2, 1950, Battery B of the 99th Artillery Battalion, to which he was attached, was subjected to enemy artillery and mortar counter battery fire, which inflicted severe casualties. As the shelling continued Captain Brune, disregarding his own safety, moved an ambulance into the battery position and directed evacuation of the wounded. As the ambulance was being loaded he rendered medical treatment throughout the area although continually exposed to shellfire. When the battery was withdrawn to a more tenable position, he effected the complete evacuation of all dead and wounded personnel.

CAPT. GENE E. LAM

The Bronze Star Medal with "V" device was recently awarded to Capt. Gene E. Lam, formerly of Glenrock, Wyo., "for heroic achievement on August 12 in the vicinity of Kang-Ni, Korea," when a Battalion Aid Station was subjected to enemy artillery fire. Captain Lam aided in the evacuation of wounded patients to safety, moving through continuous artillery fire in order to accomplish this mission. He returned to the building that housed the aid station to remove critically needed medical supplies and discovered three wounded men still in the building. He immediately started emergency treatment, removing two patients from the building and administering plasma to the third. Enemy artillery continued to fall on the building during the treatment of this last patient. Only when the treatment was completed and the patient could be moved did Captain Lam leave the building with his patient.

CAPT. WILLIAM O. HEDBERG

The Bronze Star Medal was recently awarded to Capt. William O. Hedberg, formerly of Fort Atkinson, Wis., "for heroic achievement near Kumchon, Korea, on September 25." During an attack by Company A, 5th Regiment, when casualties were mounting, he left his position of relative safety and moved into the open in order to care for the wounded. Under intense fire from tanks, mortars and machine guns, he went about his task with utter disregard for his own safety. His coolness under fire instilled courage in the wounded, and his heroic actions were an inspiration to those fighting about him.

Navy

Ships Doctors Wanted

The Military Sea Transportation Service, Atlantic, is accepting applications for civilian positions of ships doctors aboard Navy transports. These transports are operated by the Navy for the International Refugee Organization in connection with the resettlement of displaced persons from Europe to various countries throughout the world. Doctors who are accepted for such employment join their ships at New York and sail for Europe and thence to various ports throughout the world. Voyages generally are of 90 days' duration with vessels returning to New York. The salary is $6,350 per annum plus maintenance. Applicants may apply for one or more voyages and are not bound to serve beyond one voyage. Applicants are required to have a current license to practice medicine or surgery issued under the authority of a state or territory of the United States or the District of Columbia, to be graduates of an approved school of medicine and to have completed at least one year of general rotating internship. Candidates must be United States citizens and be available to leave on short notice. Minimum age requirements are 25 to 55. Information may be obtained from the Employment Branch, Industrial Relations Division, Military Sea Transportation Service, Atlantic, Fifty-Eighth Street and First Avenue, Brooklyn 20.

MEDICAL NEWS

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

Dr. Gorgas Named to Hall of Fame.—Dr. William Crawford Gorgas, who destroyed breeding places of yellow fever mosquitoes in the Panama Canal Zone and thus made possible the building of the canal, was elected in November to the Hall of Fame for Great Americans at New York University. He was one of six elected from 186 nominated by private citizens throughout the country. These elections are held every five years. Only seven can be added in any one election, and candidates must have been dead at least 25 years. Only six nominees received the necessary majority in the 1950 election. Dr. Gorgas, an officer of the Army Medical Corps, attained the rank of surgeon general. The Gorgas Memorial Institute of Tropical and Preventive Medicine, Washington, D. C., and the Gorgas Memorial Laboratory of Tropical Research in Panama were established in his honor.

CALIFORNIA

Prosthesis Institute.—An institute on upper extremity prosthetics will be held on the Los Angeles campus of the University of California January 22-26. The purpose of the conference is to demonstrate the technics of fitting, equipping and harnessing upper extremity prosthetics. For information address the Department of Institutes and Lectures, University of California Extension, Los Angeles 24.

COLORADO

Limited Private Practice for Faculty Members.—Delegates to the annual meeting of the Colorado State Medical Society have approved a set of principles under which salaried physicians of the University of Colorado School of Medicine will be permitted to accept a limited amount of private practice. At Reference Committee hearings Director Ward Darley stated that salaried professors should accept only patients referred to them by colleagues in private practice. Off-campus offices and private hospitals would be used for this added activity of "full time" faculty members. Salaries would be properly adjusted, enabling the medical school to save enough to help increase the incomes of preclinical faculty members. Regents and the medical school administration plus an advisory committee of private practitioners and clinical and preclinical faculty members are to work out details of procedure.

DELAWARE

State Medical Election.—At the October meeting of the Medical Society of Delaware the followinig officers were elected for 1951: Dr. Charles E. Wagner, Wilmington, president; Dr. Ervin L. Stambaugh, Lewes, president-elect; Dr. Benjamin F. Burton Jr., Dover, vice president; Dr. Andrew M. Gehret, Wilmington, secretary, and Dr. Joseph M. Messick, Wilmington, treasurer.

FLORIDA

Midwinter Seminar.—The fifth annual University of Florida Midwinter Seminar in Ophthalmology and Otolaryngology will be held again at Miami Beach, January 15-20. The lectures on otolaryngology will be presented on January 15, 16 and 17 and those on ophthalmology on January 18, 19 and 20. Lecturers for the courses in otolaryngology will include Drs. Louis H. Clerf, Philadelphia; Gordon D. Hoople, Syracuse; Dean M. Lierle, Iowa City; Benjamin Spector, Boston, and George Shambaugh, Chicago. Ophthalmologists who will lecture include Conrad Berens, New York; Raymon Castroviejo, New York; Jack S. Guyton, Baltimore; Harold G. Scheie, Philadelphia, and Edmund B. Spaeth, Philadelphia.

The university will be host January 17 to the Southern Section meeting of the American Laryngological, Rhinological and Otological Society. Among the speakers at this meeting will be Dr. Chevalier L. Jackson of Philadelphia. On Wednesday evening all registrants are invited to attend the Midwinter Convention of the Florida Society of Ophthalmology and Otolaryngology meeting concurrently with the seminar. A certificate of attendance to this convention will be issued for deduction purposes.

ILLINOIS

Hospital News.—St. Francis Hospital, Evanston, celebrated its golden anniversary October 10.—Ceremonies dedicating a new addition to the Rockford Municipal Tuberculosis Sanatorium were held October 3, with Governor Adlai E. Stevenson giving the principal address. With the new addition the sanatorium will have a capacity of 104 beds, providing treatment for tuberculosis patients in all stages of the disease. The building was constructed at a cost of about a million dollars.

Chicago

Fellowships in Pediatric Cardiology.—The pediatric cardiology department of the Children's Division of Cook County Hospital is accepting applications for fellowships for immediate appointment. The department offers large material of both congenital and acquired diseases of the heart; over 500 cases of congenital malformations of the heart have been studied in the past three years. There is a complete department of angiocardiography and catheterization. Salary is commensurate with experience. Information may be obtained from Dr. Rowine H. Brown, assistant medical superintendent, Children's Division of the Cook County Hospital, 700 South Wood Street, Chicago 12.

Chest Physicians and Tuberculosis Society Meeting.—A joint meeting of the Illinois Chapter of the American College of Chest Physicians and the Chicago Tuberculosis Society will be held at the Congress Hotel December 15. Dinner at 6:30 p. m. will be followed by the scientific program at 8:00 p. m. "The Use of ACTH and Cortisone in Asthma" will be discussed by Drs. Samuel M. Feinberg, Thurman B. Dannenberg, Alan R. Feinberg and Saul Malkiel, all of Northwestern University. "Clinical and Laboratory Effects of ACTH and Cortisone on Patients with Pulmonary Tuberculosis" will be presented by Dr. Smith Freeman of Northwestern University and Dr. Jennings Fershing, resident physician at Hines Hospital. All physicians are invited to attend.

INDIANA

University Appointment.—Dr. Paul R. Lurie, research fellow of the National Heart Institute, Bethesda, Md., has been appointed assistant professor of pediatrics at the Indiana University School of Medicine, Bloomington-Indianapolis. Dr. Lurie joined the staff of the Yale University School of Medicine, New Haven, Conn., after military service during World War II. He has been at the national institute for the past two years.

Course for Medical Librarians.—Indiana University is offering a new Bachelor of Science degree in Medical Record Library Science, providing three years of study on the Bloomington campus and one year's study at the university medical center in Indianapolis. The course, to be directed by Miss Gertrude Gunn, head of the department of medical records at the medical center, will qualify graduates for positions as medical record librarians in hospitals where detailed records are maintained on each patient.

KENTUCKY

Clinic Dedicated to Retired Dean.—The remodeled west wing of the Louisville General Hospital is now officially known as the John Walker Moore Clinic in honor of Dr. Moore, retired dean of the University of Louisville School of Medicine. At the dedicatory services Dr. Moore was paid tribute by his friends and associates.

Medical Scholarship Fund.—The Board of Trustees of the Rural Kentucky Medical Scholarship Fund held a meeting October 29 at Mammoth Cave and approved eight students for financial assistance to further their medical education, if and when they obtain admission to accredited medical schools. Two students already in medical school were granted loans. The money available for loans approximating $150,000 was raised by subscription in 1946 and 1947. Up to the present time 92 loans totaling $63,900 have been granted to 49 students. Of the 13 graduates, five are interns, seven are practicing in rural communities and one is in the Navy.

MAINE

State Journal Honors Dr. Higgins.—The October issue of the *Journal of the Maine Medical Association* is dedicated to Dr. Everett C. Higgins of Lewiston, who for the past 30 years has practiced medicine in central Maine and has contributed greatly to the development of the Central Maine General Hospital. Earlier the hospital honored him at a birthday dinner.

MARYLAND

Dr. Sayers Joins Baltimore Health Department.—Dr. Royd R. Sayers, formerly a medical director in the U. S. Public Health Service, was appointed on September 20 to a new part time post in the Baltimore City Health Department that was established by the Board of Estimates to strengthen the city's control of occupational diseases. Dr. Sayers comes to Baltimore after being on the U. S. Public Health Service staff since 1913. From 1940 to 1947 he was assigned to serve as director of the Bureau of Mines.

MASSACHUSETTS

Health Protection Clinic.—Of the first 2,000 "apparently healthy" persons screened at Boston's Health Protection Clinic, a total of 1,266, or 63 per cent, were referred to their family physicians for both known and unknown conditions, and of this total, 1,117 were referred for previously unknown physical defects. The clinic was opened at the New England Center Hospital in Boston in December 1949. Sponsored by the Massachusetts Medical Society and financed by the state health department, the clinic provides free screening for heart disease, cancer and high blood pressure. Dr. Claire F. Ryder, Boston, state health department, is administrator Of the 1,730 conditions discovered at the clinic, the major category was obesity, defined as being more than 20 per cent above the ideal weight. Poor vision accounted for 212 defects. Among the more serious ailments were heart disease (159 cases), diabetes (47), tuberculosis (17), syphilis (8), high blood pressure (173), kidney disease (10) and hearing defects (140). Reopened on October 3, the health protection clinic is now receiving requests for appointments. Information may be obtained from Dr. Claire F. Ryder, New England Center Hospital, Boston 11. The telephone number is Liberty 2-2855.

MISSOURI

Grant for Cancer Teaching and Research.—Washington University School of Medicine, St. Louis, in October received a check for $39,000 from the American Cancer Society for continuation of the program of cancer teaching and research through Aug. 31, 1951. In addition to the institutional grant, Washington University is the recipient of grants-in-aid to the amount of $36,992 and fellowships totaling $5,800, bringing the total amount of financial assistance of the American Cancer Society to Washington University this year to $81,792.

University Appointment.—Dr. Walter G. Rice has been appointed assistant professor of pathology and associate director of clinical pathology for the St. Mary's Group of Hospitals of the Saint Louis University School of Medicine. Dr. Rice will work with Dr. Henry Pinkerton, director of the department of pathology at Saint Louis University, and Dr. Raymond O. Muether, director of clinical pathology at the St. Mary's Group of Hospitals. Dr. Rice comes to the university from Texas, where he was assistant director of laboratories at Baylor University Hospital and instructor in clinical pathology at Southwestern Medical School of the University of Texas, Dallas. After five years' war service he was assistant to the national director of the Canadian Red Cross and Blood Transfusion Service.

NEW JERSEY

Personal.—Dr. Nolan D. C. Lewis, director of the New York State Psychiatric Institute and Hospital, New York, has been named chairman of the Committee on Mental Health for the State Charities Aid Association.

Executive Secretary to Head Medical Service Plan.—Mr. James E. Bryan, Trenton, who has been the Medical Society of New Jersey executive secretary since 1947, has been appointed administrator of the Medical-Surgical Plan of New Jersey, the "Blue Shield" medical care plan, effective November 1. He will have charge of the administrative details of the plan as well as its relations with physicians and the public in all nonprofessional matters. Mr. Bryan has been engaged in medical society executive, editorial and public relations work for 18 years in New York and New Jersey.

NEW YORK

Whipple Auditorium Dedicated.—More than 250 graduates of the University of Rochester School of Medicine and Dentistry attended ceremonies at Strong Memorial Hospital October 12 dedicating an amphitheater of the medical school as "George H. Whipple Auditorium." Dr. Whipple has been dean of the school since it was founded 25 years ago. The ceremonies were part of a three day medical program of the school's alumni association.

Preconception Clinic.—A new clinic for the "preconception" treatment of couples who have histories of unsatisfactory pregnancies has been established at the Syracuse Dispensary. Three categories of patients are being treated: (1) patients with histories of previous premature labors, (2) chronic aborters and (3) patients with histories of congenitally defective offspring. Both husband and wife are thoroughly studied to ascertain correctable pathological conditions. Indicated therapy will then be instituted to correct such conditions prior to conception. It is hoped that this pilot study will lead to methods that may be generally employed in private practice. The clinic is a joint venture of Syracuse University College of Medicine and the Syracuse Department of Health. It is sponsored by the Bureau of Maternal and Child Health of the New York State Department of Health. It has the approval of the Maternal Welfare and Infant and Child Health Committees of the Onondaga County Medical Society as well as the Central New York Obstetrical and Gynecological Society. Miss Nancy Cochrane, tenth floor, Memorial Hospital, is in charge of appointments.

New York City

Dr. Rusk Gives Hauswirth Lecture.—The second annual Louis Hauswirth Lecture in Medicine, sponsored by the Beth David Hospital Alumni Association, was given by Dr. Howard A. Rusk, director of the Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, November 29 at the Beth David Hospital, on "A Dynamic Approach to Medicine's Number One Problem."

New York Diabetes Association.—At its annual meeting on November 10 the New York Diabetes Association made Dr. Henry Dolger of Mount Sinai Hospital its president, Dr. Herbert Pollack, secretary, and Mr. David Handman, treasurer. The association provided a one month vacation for 154 children at its camp last summer; 20 of the staff also were diabetic. This year four new cabins, accommodating 10 children and two counselors each, were constructed for girls. Many improvements were made, including new docks for the boats and canoes, a new medical building for the administration of insulin and a new laundry building.

Grant to Train Plastic Surgeons.—A grant of $27,000 from the Milbank Memorial Fund to train plastic surgeons has been made to New York University-Bellevue Medical Center. This is the last of the fund's several grants to the Medical Center intended to promote the rehabilitation of handicapped persons. The plastic surgery grant will make possible three fellowships for the training of young surgeons in the plastic surgery unit, under the direction of Dr. John M. Converse. In its research and training program the plastic surgery unit is working in close association with the medical center's Institute of Physical Medicine and Rehabilitation, to which the Milbank Memorial Fund has also made contributions.

Physicians Art Club.—At the seventeenth annual dinner meeting of the New York Physicians Art Club, November 6, Dr. Benjamin F Morrow was elected president, Dr. Solomon Fineman vice president and Dr. William Snow secretary-treasurer. It is hoped that many more physicians will participate in the activities of the club. The recent exhibition of work of the art club members, held at the Academy of Medicine, was of exceptionally high caliber. Oils, watercolors, sculpture and photography were the main mediums represented. Membership is open to all New York physicians. Those interested may join by paying $5 dues to the secretary-treasurer, Dr. William Snow, 941 Park Avenue, New York.

House Staff Educational Program.—Dr. Frode Jensen has been appointed director of the House Staff Educational Plan of the New York Committee on the Study of Hospital Internships and Residencies, which is sponsored by all six medical schools in New York. He succeeds Dr. Stuart W. Cosgriff in the educational program developed for nonteaching hospitals by the committee through a grant from the Commonwealth Fund. The House Staff Educational Plan, endorsed by the New York Academy of Medicine and the Coordinating Council of the Medical Societies of all the counties of New York City, now is self sustaining and continues to provide a strong educational stimulus for the training of staff members in the field of medicine in those hospitals not affiliated with the local medical schools. Dr. Jensen, newly appointed assistant dean of New York University Post-Graduate Medical School, recently completed three years as director of the Office of Graduate and Postgraduate Medical Education at the University of Colorado School of Medicine, Denver.

OHIO

Dr. Ransohoff Retires.—After 45 years of volunteer teaching in the University of Cincinnati College of Medicine, Dr. J. Louis Ransohoff has retired under the university's automatic retirement rule. He will remain in practice. The university board of directors has granted him the honorary faculty title of clinical professor emeritus of surgery.

Taylor Memorial Fund.—A committee has established the Lester H. Taylor Memorial Fund for the purpose of receiving gifts from Dr. Taylor's friends. The fund is directed toward strengthening the financial security of the museum. Friends and patients have contributed about $30,500, which will eventually be devoted to an appropriate memorial to the late Dr. Taylor, the museum's first president.

VERMONT

University Appointments.—Dr. William E. Brown, dean of the University of Vermont College of Medicine, Burlington, has been appointed to serve as staff associate with the Survey of Medical Education, Inc., on a part time basis. He will remain at the college. Dr. Theodore H. Harwood, associate professor of medicine at the college, has been appointed assistant dean. Dr. George A. Schumacher, New York, has joined the faculty of the college of medicine as professor of neurology. He was formerly on the faculty of Columbia University College of Physicians and Surgeons, New York.

WISCONSIN

Cerebral Palsy Clinic.—The Cerebral Palsy Clinic of the Medical Society of Milwaukee County opened in October in offices in the Goodwill Industries Building in Milwaukee. The medical director is Dr. Raymond C. Waisman. The clinic is open Monday morning, Wednesday afternoon and Friday morning. An occupational and a physical therapist are full time employees. They came to the clinic after taking a specialized postgraduate course of cerebral palsy training with Dr. Winthrop M. Phelps at Cockeysville, Md.

PUERTO RICO

Annual Medical Meeting.—The annual assembly of the Medical Association of Puerto Rico will be held December 12-17 with headquarters at the association building, Avenida Fernández Juncos-Parada 19, Santurce, under the presidency of Dr. A. Oliveras-Guerra. The first day will be devoted to papers on cancer. Guest speakers are as follows:

Brewster Miller, New York, Opening Remarks.
C. Langdon Parsons, Boston, Present Concepts of Cancer of the Cervix.
Juan A. Del Regato, Colorado Springs, Colo., Indications for Radiotherapy of Cancer.
Grantley W. Taylor, Boston, Management of Regional Lymph Node Metastases.
Wilburt C. Davison, Durham, N. C., Cancer in Childhood.
Douglas H. Sprunt, Memphis, Tenn., Evaluation and Application of Tests for the Diagnosis of Cancer.

The program is being given under the auspices of the Puerto Rico Chapter of the American Cancer Society, the insular department of health and the association. The Wednesday morning program will be a symposium on the Practical Applications of the Newer Drugs, ACTH and Cortisone.

At the Thursday session, planned in cooperation with the Puerto Rico Chapter of the American College of Chest Physicians, the invited speakers will be:

Pedro Domingo, Havana, Cuba, Newer Aspects on the Defense of the Body Against Bacterial Infection.
Louis H. Clerf, Philadelphia, The Esophagus and Its Diseases.

Other guest speakers at the sessions include:

Frank H. Lahey, Boston, Management of Diseases of the Thyroid.
Leo Meyer, New York, Medical Aspects of Nuclear Energy.
L. Kraeer Ferguson, Philadelphia, Surgical Aspects of Ulcerative Colitis and Regional Enteritis.
Henry L. Bockus, Philadelphia, Treatment and Prognosis in Hepatic Cirrhosis.
Leonard J. Piccoli, Ph.D., New York, Recent Developments in Vitamin B_{12} Therapy.
Paul Gyorgy, Philadelphia, News from the Nutritional Front.
Howard A. Rusk, New York, Rehabilitation in Chronic Diseases.
Lewis C. Scheffey, Philadelphia, Diagnosis and Management of Pelvic Malignancy.
Reed M. Nesbit, Ann Arbor, Mich., Results of Endocrine Therapy of Prostatic Cancer: Diagnostic Implication of Serum Phosphatase Determinations.

The annual banquet and dance will be held Saturday at 8:00 p. m. at the Hotel Condado. There will be technical exhibits.

GENERAL

Postgraduate Medical Studies in Britain.—Dr. Julian Landman of London, a leading authority on British postgraduate medical education, will be in the United States and Canada in December and January. His address in New York will be the Waldorf-Astoria Hotel, during December. American doctors contemplating postgraduate study in Britain are advised to contact Dr. Landman.

ACTH Conference.—The second clinical conference on pituitary adrenocorticotropic hormone, planned by Armour and Company, Chicago, is being held at the Palmer House, Chicago, December 8-9. This conference brings together some 300 men and women who have been testing the hormone in various disease conditions and seeking data on its mode of action. A total of 95 papers will be presented. The reports come from leading clinics in all parts of the United States and from England, France, Canada, Mexico and Australia.

Dr. Cori Wins Borden Award.—Dr. Gerty F. Cori, Washington University School of Medicine, St. Louis, received the Borden Foundation award for outstanding medical research at the meeting of the Association of American Medical Colleges at Lake Placid, New York, in October. The award goes annually to a staff member of an American medical college for outstanding and significant work in medical research. Dr. Cori received it for her discovery of a new enzyme. She and her husband, Dr. Carl T. Cori, were Nobel Prize winners in 1947 for their work in carbohydrate chemistry.

International Symposium on Steroids.—A symposium on steroids will be held in Cuernavaca, Mexico, January 15-18, under the auspices of a committee of industrial and institutional scientists. Membership is limited by invitation to persons nominated either by the committee from the United States or by the Mexican subcommittee. The proceedings of the conference will be recorded and will be published as rapidly after the close of the sessions as possible.

The sponsoring committee comprises Dr. Konrad Dobriner, Sloan-Kettering Institute for Cancer Research, New York; Dr. Paul Holbrook, Tucson, Ariz.; Gregory G. Pincus, Sc.D., Worcester Foundation for Experimental Biology, Shrewsbury, Mass.; Dr. Edward C. Reifenstein Jr., Research Institute, Oklahoma Medical Research Foundation, Oklahoma City; I. V. Sollins, Chemical Specialties Co., Inc., New York, and Syntex S. A., México, D. F. The invited group includes clinical workers in rheumatology, cancer and other diseases, as well as experimental workers in the fields of biology, biochemistry and pharmacology.

Prize in Public Health Methodology.—Annual recognition in the form of a $500 award and a plaque will be made available next year for outstanding work in methodology research. The prize, to be known as the Kimble Glass Methodology Research Award, is to be given by the Conference of State and Provincial Public Health Laboratory Directors and is endowed by Kimble Glass, Division of Owens-Illinois Glass Company. Its purpose is to give recognition and reward to a person who has contributed outstandingly in developing a new or better method of procedure in the field of public health work. Methodology research has to do with the devising of methods of applying scientific knowledge in the solution of medical and public health problems. Selection of the outstanding work and awarding of the prize will be under the direction of an award's committee, which includes Samuel R. Damon, Ph.D., director of laboratories, Indiana State Department of Health, Indianapolis; Dr. Malcolm Merrill, director of laboratories, California State Department of Health, Berkeley; Francis C. Lawler, Sc.D., director of laboratories, Vermont State Department of Health, Burlington; Martin Frobisher, Sc.D., chief of bacteriology, Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga.; Dr. Geoffrey Edsall, professor of bacteriology, Boston University School of Medicine, and Dr. Albert V. Hardy, director of laboratories, Florida State Board of Health, Jacksonville.

Inter-American Congress on Brucellosis.—The Third Inter-American Congress on Brucellosis, held in Washington, D. C., November 6-10, was attended by nearly 200 delegates and observers from 22 countries and possessions, including 10 countries of Latin America, and from 28 states and the District of Columbia in the United States, as well as from two specialized agencies of the United Nations. The delegates to the congress discussed developments in the diagnosis of brucellosis and its prevention through vaccination of animals. Although only 4,000 to 6,000 cases of human brucellosis are reported annually in the United States, it is estimated by experts that there are probably 40,000 to 100,000 new cases of brucellosis annually in the United States. Because of the lack of standardization of diagnostic technics and the many forms that the disease may take, the great majority of cases are not at present discovered It was announced that the two United Nations agencies concerned with the problem of brucellosis, WHO and FAO, have organized brucellosis centers in eight countries in Europe, South Africa and Australia and are planning similar centers in the United States, Mexico, two South American countries and India

Officers elected at the congress are Dr Wesley W Spink, Minneapolis, president, and the following vice presidents Dr Enso Criscuola, Argentina, Dr Maximiliano Ruiz Castaneda, Mexico, Dr Genesio Pacheco, Brazil, Leslie M Hutchings, D V M, Lafayette, Ind, C H Mitchell, Canada, and Dr. Birdsall N Carle, Bethesda, Md

The first international Expert Panel on Brucellosis was held November 11-13 It was arranged jointly by FAO and WHO and was composed of 26 members and six observers representing 11 countries Sir Weldon Dalrymple-Champneys, deputy chief medical officer of the United Kingdom Ministry of Health, London, was elected chairman Dr Castaneda, of the General Hospital in Mexico City, and Dr Hutchings, department of veterinary medicine, Purdue University, Lafayette, Ind, were elected vice chairmen

CORRECTION

Pancreatic Glucagon.—In the abstract on this subject in The Journal of Nov 25, 1950, page 1131, the second word in line 23 and the first word in line 24 should have been "sugar," not "pressure"

National Advisory Neurological Diseases and Blindness Council.—The Scientific Reports Branch of the National Institutes of Health, Bethesda, Md, writes that owing to an error on their part, Dr Percival Bailey, of the University of Illinois Medical College, was announced as a member of this council This announcement was published in The Journal Nov 25, 1950, page 1100

DEATHS

MacConnell, John Wilson ⊕ Davidson, N. C.; born in McConnellsville, S. C., Jan. 11, 1878; University of Maryland School of Medicine, Baltimore, 1907; formerly vice president of the Federation of State Medical Boards of the United States and member of the board of medical examiners; in 1908 joined the faculty of Davidson College, where he organized the department of biology and where he served as professor of biology, professor of physiology and hygiene and director of the student health service; member of the Southern Medical Association, Military Order of World War, Sigma Alpha Epsilon, Nu Sigma Nu, Phi Beta Kappa and Omicron Delta Kappa; at one time third vice president of the Association of Surgeons of the Southern Railway System; a first lieutenant in the medical corps of the U. S. Army on the Mexican border in 1916; later served with the American Expeditionary Forces during World War I; affiliated with Lowrance Hospital in Mooresville and the Charlotte Eye, Ear, Nose and Throat Hospital in Charlotte; died September 26, aged 72, of uremia.

Bryan, Alanson Leroy ⊕ Medical Director, Captain, U. S. Navy, retired, San Diego, Calif.; born March 4, 1892, in Dixon, Iowa; Vanderbilt University School of Medicine, Nashville, Tenn., 1916; was first appointed assistant surgeon in the Naval Reserve in 1916 and was commissioned lieutenant (jg) in the medical corps of the U. S. Navy in April 1917, when he reported for active duty; served at many hospitals in the United States and was medical officer in command of the Naval Hospital at Dublin, Ga., from 1944 through 1945; served on the *USS Fulton, Memphis, Procyon, Chaumont, Medusa, Maryland, Lafayette, Massachusetts* and *Relief;* for services performed aboard the *USS Relief* from December 1942 to March 1944 and as medical officer in command of the Naval Hospital at Dublin was awarded a letter of commendation from the Secretary of the Navy; fellow of the American College of Surgeons; retired Jan. 1, 1947 for physical disability; died in the U. S. Naval Hospital October 12, aged 58, of cerebral hemorrhage and malignant hypertension.

Mentzer, Stanley Herman, San Francisco; born in San Francisco April 9, 1897; University of California Medical School, San Francisco, 1923; entered the Mayo Foundation in Rochester, Minn., as a fellow in surgery in July 1923; left the foundation in July 1926; formerly assistant clinical professor of surgery at the University of California Medical School; specialist certified by the American Board of Surgery; past president and formerly secretary of the San Francisco County Medical Society; fellow of the American College of Surgeons; member of the Royal Society of Tropical Medicine and Hygiene, American Society of Tropical Medicine, the Pan American Medical Association, Osler Medical Association and the International Association of Medical Museums; served on the staffs of San Francisco, St. Joseph's and Hahnemann hospitals; died October 6, aged 53, of cerebral hemorrhage and hypertension.

Patek, Arthur Jackson ⊕ Milwaukee; born in Milwaukee Nov. 11, 1868; University of Pennsylvania Department of Medicine, Philadelphia, 1892; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past president of the State Medical Society of Wisconsin, which in 1935 presented its award to him for distinguished service to the society, Medical Society of Milwaukee County and the Milwaukee Academy of Medicine; formerly preceptor in charge, University of Wisconsin Medical School; served during World War I; affiliated with Columbia, Milwaukee and Mount Sinai hospitals; founder and for several years editor of the *Wisconsin Medical Journal;* director of the Milwaukee Orchestral Association; died in Columbia Hospital October 12, aged 81, of monocytic leukemia.

Lewey, Frederic Henry ⊕ Philadelphia; born in Berlin, Germany, Jan. 28, 1885; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Germany, 1908; associate professor of neuropathology and research associate in audiology at the University of Pennsylvania School of Medicine and professor of neuroanatomy at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; specialist certified by the American Board of Psychiatry and Neurology; member of the American Neurological Association, American Association of Neuropathologists and the Association for Research in Nervous and Mental Diseases; served during World Wars I and II; affiliated with the Hospital of the University of Pennsylvania; died in Pennsburg October 5, aged 65, of coronary thrombosis.

Dumas, Alexander George, Minneapolis; born in Minneapolis May 11, 1896; Creighton University School of Medicine, Omaha, 1921; clinical associate professor of psychiatry at the University of Minnesota Medical School; member of the American Psychiatric Association; formerly associated with the Veterans Administration Clinic; recently resigned as chairman of the governor's mental health advisory committee of which he had been one of the founders; served as medical director, Minnesota Mental Hygiene Society; formerly consultant to municipal courts of Hennepin County; at one time chief of staff of Glenwood Hills and Homewood hospitals; died in University Hospital October 2, aged 54, of hypertension and cerebral vascular accident.

Bottorff, Melvin Kinch ⊕ Lake Village, Ark.; University of Arkansas School of Medicine, Little Rock, 1932; served during World War II; alderman; died in Helena (Ark.) Hospital September 26, aged 44, of uremia, chronic nephritis and malignant hypertension.

Bowser, Willard Parker, Berea, Ohio; Western Reserve University School of Medicine, Cleveland, 1918; served on the staffs of St. John's and Deaconess hospitals in Cleveland and Berea Community Hospital; died September 23, aged 56, of cerebral hemorrhage.

Carrell, John B., Hatboro, Pa.; Jefferson Medical College of Philadelphia, 1876; member of the American Medical Association and in 1915 a member of the House of Delegates; at one time served as school director; member of the Montgomery County Historical Society; for many years editor of the *Bucks County Medical Bulletin;* in 1946 awarded the Good Citizenship Medal of the Philadelphia Chapter of the Sons of the American Revolution; died in the Abington (Pa.) Memorial Hospital September 20, aged 99, of injuries received in a fall.

Carter, Albert Howard, Oak Park, Ill.; Jenner Medical College, Chicago, 1906; member of the American Medical Association; served during World War I; died October 8, aged 66, of cardiac decompensation and an accidental fall.

Chapman, George Little, Toledo, Ohio; Miami Medical College, Cincinnati, 1899; served overseas during World War I; formerly on the staff of Flower Hospital; died in Toledo Hospital October 1, aged 78, of coronary occlusion.

Coffey, Charles James ⊕ Milwaukee; University of the City of New York Medical Department, 1894; clinical professor of otolaryngology emeritus at Marquette University School of Medicine; an Associate Fellow of the American Medical Association; for many years assistant city health commissioner; served as a member of the school board, of which he had been past president; past president of the Marquette University Alumni Association; died September 30, aged 80, of coronary thrombosis and arteriosclerosis.

Cox, Thomas Edward, Washington, D. C.; University of West Tennessee College of Medicine and Surgery, Memphis, 1916; served during World War I; died in Freedmen's Hospital October 7, aged 58, of intraventricular hemorrhage and hypertension.

Craft, Harold Albert, Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1937; member of the American Medical Association; at one time on the faculty of his alma mater; certified by the National Board of Medical Examiners; affiliated with George Washington University, Columbia, Doctors, Emergency, Sibley and Homeopathic hospitals; died September 27, aged 48, of coronary thrombosis.

Daniels, Melvin Robert Micheal, Yonkers, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1944; certified by the National Board of Medical Examiners; served during World War II; interned at the Metropolitan Hospital in New York and served a residency in pathology at the Veterans Administration Hospital in New York; died September 23, aged 33, when a small seaplane he was piloting crashed.

Darnall, Moses Hubbard, Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1907; served during World War I; died in Veterans Administration Hospital, Perry Point, Md., September 27, aged 68, of coronary sclerosis.

Davis, Irwin Grant ⊕ Rushford, Minn.; Rush Medical College, Chicago, 1914; for many years health officer of Peterson and Rushford; served during World War I; on the staff of Cottrel Maternity Hospital; died September 29, aged 62, of ruptured abdominal aortic aneurysm.

⊕ Indicates Fellow of the American Medical Association.

Day, Clark W. ⊕ Indianapolis; Physio-Medical College of Indiana, Indianapolis, 1901; served as police surgeon; formerly member of the board of health; during World War II cited by the President for his work as medical examiner for the Selective Service; member of the staffs of St. Vincent's Hospital and Methodist Hospital, where he died September 23, aged 74, of hypertension and arteriosclerotic heart disease.

De Korven, Victoria K., St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1909; St. Louis College of Physicians and Surgeons, 1911; died in St. Vincent's Sanitarium September 27, aged 80, of primary atypical pneumonia, following a fractured hip received in a fall.

Dixon, Charles Leonard, Renton, Wash.; Jefferson Medical College of Philadelphia, 1895; member of the American Medical Association; health officer of Renton; served as county health officer; director of the Peoples National Bank; died September 23, aged 79, of injuries received in an automobile accident.

Dorne, Maurice ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1916; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; associate in dermatology at Northwestern University Medical School; served during World War I; affiliated with Mount Sinai Hospital and Alexian Brothers Hospital, where he died September 24, aged 57, of cerebral hemorrhage.

Eisenberg, David, New York; Long Island College Hospital, Brooklyn, 1908; affiliated with Sydenham and Harlem hospitals; died in Mount Sinai Hospital September 18, aged 64, of coronary occlusion.

Erpelding, John Kenneth, Saginaw, Mich.; Jefferson Medical College of Philadelphia, 1921; served as chief of the Civilian Dispensary, Brookley Air Force Base, Mobile, Ala.; recently appointed to the staff of Saginaw County Hospital; died in St. Mary's Hospital September 18, aged 57, of peritonitis and bronchogenic carcinoma.

Ford, James Arthur, Orlando, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1916; during World War II served as medical examiner for the Selective Service System and was the recipient of several certificates of merit, including a Congressional award; died in Johns Hopkins Hospital, Baltimore, September 23, aged 58.

Foster, Ruth ⊕ New York; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1931; member of the American Psychiatric Association; died September 29, aged 56, of carcinoma.

French, Oscar Witters ⊕ Coalville, Utah; Rush Medical College, Chicago, 1893; formerly vice president of the Utah State Medical Association, of which he had been honorary president since September 1948; served as mayor; died September 16, aged 82, of thrombosis of the abdominal aorta.

Fretz, John Lewis ⊕ Seattle; Rush Medical College, Chicago, 1934; an associate of the International College of Surgeons; member and past president of the Seattle Academy of Surgery; member of the Washington State Obstetrical Association; member of the U. S. Committee for the World Medical Association; served on committee for health, Seattle Municipal League; affiliated with Seattle General Hospital and Virginia Mason Hospital; killed when his private plane crashed at Renton Airport September 22, aged 51.

Galligan, Edward Joseph, Taunton, Mass.; College of Physicians and Surgeons, Baltimore, 1896; member of the American Medical Association; formerly city physician; affiliated with Morton Hospital; died September 25, aged 81, of arteriosclerotic heart disease.

Garland, Harrie Sanborn, Pasadena, Calif.; University of Nebraska College of Medicine, Omaha, 1905; died September 21, aged 67, of coronary thrombosis.

Girdwood, John ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1894; served overseas during World War I; for many years medical examiner for the City Service Commission; died September 25, aged 79, of heart disease.

Grayson, William Friar, Granite City, Ill.; St. Louis College of Physicians and Surgeons, 1898; member of the American Medical Association; formerly state health officer; served during World War I; affiliated with St. Elizabeth Hospital; died September 20, aged 76, of uremia.

Hartzell, Harry Wallace, National City, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; died in Paradise Valley Sanitarium and Hospital September 25, aged 70, of coronary thrombosis.

Hemmings, Lincoln Smith, Bernalillo, N. Mex.; University of Wooster Medical Department, Cleveland, 1914; member of the American Medical Association; died in Albuquerque, N. Mex., September 30, aged 60, of coronary thrombosis.

Hershner, Newton W., Mechanicsburg, Pa.; University of Maryland School of Medicine, Baltimore, 1906; member of the American Medical Association; past president of the Cumberland County Medical Society; for many years medical director of Cumberland County; served on the staffs of the Harrisburg (Pa.) Hospital and the Carlisle (Pa.) Hospital; vice president of the First Bank and Trust Company, where he was a member of the board of directors for many years; died October 8, aged 72, of coronary occlusion.

Hirsch, Jerome Byron ⊕ Greenville, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; served overseas during World War I; affiliated with King's Daughters Hospital, where he died October 5, aged 65, of cerebral hemorrhage.

Horn, John Wesley Jr., ⊕ Hummelstown, Pa.; Temple University School of Medicine, Philadelphia, 1917; served as deputy coroner and member of the school board; director of the Farmers' Bank of Hummelstown; died September 29, aged 63, of coronary occlusion.

Hull, Chester E., Fort Wayne, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; died October 2, aged 67, of intestinal obstruction and cancer.

Hunt, Harry Elwyn, State Soldiers Home, Ohio; Cleveland Homeopathic Medical College, 1899; veteran of the Spanish-American War; died in Ohio Soldiers and Sailors Home Hospital October 1, aged 78, of cerebral hemorrhage.

Ives, Nathaniel Holmes ⊕ Mount Vernon, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1895; in 1945 was made an honorary life member of the board of managers of Mount Vernon Hospital in recognition of fifty years' service to the hospital; a trustee of his alma mater; for many years director of the Mount Vernon Trust Company; died in the Lawrence Hospital, Bronxville, October 8, aged 77.

Jacobius, Lawrence, New York; Albany Medical College, 1914; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; affiliated with the Hospital for Joint Diseases, Harlem Hospital and Jewish Memorial Hospital; died September 26, aged 59, of rupture of the abdominal aorta.

Jones, Richard Wayland, Yreka, Calif.; Jefferson Medical College of Philadelphia, 1935; member of the American Medical Association; on the staff of the Siskiyou County General Hospital; died September 24, aged 41, of coronary occlusion.

Karr, Maskell Curwen, Akron, Ohio; Eclectic Medical Institute, Cincinnati, 1909; died September 16, aged 67, of coronary occlusion.

Kimbrough, William Edward, Chatom, Ala.; University of Alabama School of Medicine, University, 1915; member of the American Medical Association; served during World War I; died October 8, aged 60, of coronary occlusion.

King, David Francis ⊕ Laurelton, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1874; an Associate Fellow of the American Medical Association; died September 22, aged 97, of pneumonia.

Kingston, Thomas Smith, Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886; formerly practiced in Croswell, where he served as county health officer and member of the local board of education; died in East Grand Rapids September 29, aged 89, of diverticulitis.

Kinney, Richard Anthony ⊕ Jamestown, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1930; served during World War II; died in St. Francis Hospital, Pittsburgh, September 21, aged 44.

Land, Joel Cameron ⊕ Walnut Ridge, Ark.; Memphis (Tenn.) Hospital Medical College, 1900; also a pharmacist; past president of the Lawrence County Medical Society; formerly vice president of the Arkansas Medical Society; served during World War I; health officer; physician and surgeon for the Missouri Pacific and Frisco railroads; died in Baptist Memorial Hospital, Memphis, Tenn., October 3, aged 76, of cerebral embolus.

Latham, Edgar M., Toledo, Ohio; Toledo Medical College, 1900; died September 28, aged 82, of cerebral thrombosis.

Leathers, Douglas Arnold, Indianapolis; Jefferson Medical College of Philadelphia, 1886; died October 1, aged 91, of arteriosclerotic heart disease.

Linn, Robert Fred, Lakewood, Ohio; Loyola University School of Medicine, Chicago, 1938; member of the American Medical Association; fellow of the American College of Surgeons; clinical instructor in obstetrics and gynecology at Western Reserve University School of Medicine in Cleveland, where he was on the staff of Lutheran Hospital and on the consulting staff of City Hospital; served during World War II; died September 26, aged 40, of coronary disease.

McGarry, John Louis, Coeur d'Alene, Idaho; Northwestern University Medical School, Chicago, 1937; member of the American Medical Association; formerly on the staff of St. Francis Hospital, Evanston, Ill.; died September 23, aged 40, of coronary occlusion.

Mercer, Herman A., ⊕ Jeffersonville, Ind.; born in Pretty Prairie, Kan., May 22, 1896; University of Oklahoma School of Medicine, Oklahoma City, 1922; formerly assistant in ophthalmology at the University of Illinois College of Medicine in Chicago, where he was a resident in ophthalmology at Research and Educational Hospitals; on the staff of SS Mary and Elizabeth Hospital, Louisville, Ky., and Clark County Memorial Hospital, Jeffersonville; died in Hanover, Ind., October 3, aged 54, of heart disease.

Messner, Paul Oram, Miami Springs, Fla.; College of Medical Evangelists, Loma Linda and Los Angeles, 1934; certified by the National Board of Medical Examiners; served during World War II; died in Jackson Memorial Hospital, Miami, October 2, aged 48, of cerebrovascular hemorrhage and hypertensive vascular disease.

Morse, John Hinckley, Augusta, Maine; Harvard Medical School, Boston, 1901; on the staff of Augusta General Hospital; died September 30, aged 75, of coronary occlusion.

Mosler, Ernst, New York; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1906; member of the American Medical Association; associated with Flower and Fifth Avenue Hospitals and Beth Abraham Home for Incurables; died September 21, aged 68, of carcinoma of the stomach.

Mott, Edwin Leland, Fresno, Calif.; Jefferson Medical College of Philadelphia, 1918; served during World War I; affiliated with St. Agnes and Fresno Community hospitals; burned to death in a mountain cabin fire near Fresno September 24, aged 57.

Mullikin, Hugh Mathes, Terre Haute, Ind.; Miami Medical College, Cincinnati, 1903; died October 2, aged 73, of coronary disease.

Nihizer, Adonis Hugh ⊕ Vaughnsville, Ohio; Ohio State University College of Medicine, Columbus, 1929; affiliated with Lima Memorial and St. Rita's hospitals; died September 20, aged 52, of coronary thrombosis.

O'Hara, Fred Summa, Springfield, Ill.; Marion-Sims College of Medicine, St. Louis, 1899; specialist certified by the American Board of Radiology; member of the Radiological Society of North America, of which he had been first president, the American Medical Association and the American College of Radiologists; served during World War I; affiliated with Memorial and St. John's hospitals; died October 1, aged 74, of cerebral hemorrhage.

Parmeter, Rolland Louis, Albion, Mich.; Rush Medical College, Chicago, 1895; fellow of the American College of Surgeons; formerly practiced in Detroit, where he was affiliated with Wayne University College of Medicine and was for many years on the staffs of Receiving and Harper hospitals; served during World War I; formerly editor of the *Bulletin of the Wayne County Medical Society,* now known as the *Detroit Medical News;* died in the Sheldon Memorial Hospital October 4, aged 78, of heart disease.

Peters, David Boteler ⊕ Surgeon, Lieutenant Commander, U. S. Navy, retired, Asheville, N. C.; George Washington University School of Medicine, Washington, D. C., 1917; veteran of World War I; entered the U. S. Navy in December 1930; retired June 1, 1943; died in the Veterans Administration Hospital in Oteen September 26, aged 69, of myocardial infarction and arteriosclerotic heart disease.

Poling, Owen, Mason, W. Va.; Loyola University School of Medicine, Chicago, 1916; member of the American Medical Association; died in Charleston September 27, aged 66, of carcinoma of the lung and liver.

Raiter, Roy Ferdinand, Cloquet, Minn.; born in Stillwater, Minn., Nov. 26, 1897; Northwestern University Medical School, Chicago, 1923; member of the American Medical Association; fellow of the American College of Surgeons and the International College of Surgeons; formerly associated with the Indian Service; medical superintendent of the hospital bearing his name; served on the staffs of St. Luke's and St. Mary's hospitals in Duluth and Fond du Lac Hospital; died in University Hospital, Minneapolis September 23, aged 52, of tuberculous peritonitis.

Rether, Charles Hoffman, Columbus, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1899; died in Mount Carmel Hospital September 29, aged 84, of arteriosclerotic gangrene of the left leg.

Rossell, Edward Wood, Camden, N. J.; Medico-Chirurgical College of Philadelphia, 1905; member of the American Medical Association; died September 29, aged 73, of cerebral thrombosis.

Smith, Edward Kearney, Lancaster, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1918; member of the American Medical Association and the American Academy of Pediatrics; for many years school physician; affiliated with Rossmere Sanatorium, Lancaster General and St. Joseph's hospitals; died September 12, aged 55, of cerebral thrombosis.

Stutzman, Raymond Howard, Tower City, Pa.; Maryland Medical College, Baltimore, 1912; member of the American Medical Association; affiliated with Lemos B. Warne Hospital in Pottsville, where he died September 23, aged 65, of coronary thrombosis.

Sullivan, Charles Peter ⊕ Dayton, Ohio; Northwestern University Medical School, Chicago, 1912; served during World War I; died in Woodlawn Hospital, Chicago, September 24, aged 63, of cardiac tamponade.

Terry, Wallace Irving, San Francisco; Medical Department of the University of California, San Francisco, 1892; clinical professor of surgery emeritus at his alma mater; member of the House of Delegates of the American Medical Association in 1905; member of the American Surgical Association and Pacific Coast Surgical Association, of which he had been past president; fellow of the American College of Surgeons; died September 22, aged 81, of carcinoma of the sigmoid.

Uhlmann, Robert, Kansas City, Mo.; Ludwig-Maximilians-Universität Medizinische Fakultät, Munchen, Bavaria, Germany, 1910; member of the American Medical Association; affiliated with Menorah Hospital; died September 13, aged 63, of cancer.

Voigt, Arno Constantine ⊕ Hawley, Pa.; Jefferson Medical College of Philadelphia, 1901; served as county coroner and county medical director; president of the First National Bank; affiliated with Wayne County Memorial Hospital, Honesdale, where he died September 20, aged 72, of arteriosclerosis and myocarditis.

Von Roeder, Ludwig Robert, New York; Cornell University Medical College, New York, 1900; formerly adjunct professor of pediatrics at the New York Polyclinic Medical School and Hospital; affiliated with New York Polyclinic, St. Francis and Park East hospitals; died in Lenox Hill Hospital, September 22, aged 74, of coronary thrombosis with myocardial infarction.

Walker, Wallis Dunlap ⊕ Rye Beach, N. H.; Harvard Medical School, Boston, 1901; served during World War I; died in the Exeter (N. H.) Hospital September 24, aged 74, of leukemia.

Wallace, William Smiley ⊕ Orange, Calif.; Jefferson Medical College of Philadelphia, 1893; an Associate Fellow of the American Medical Association; past president of the Orange County Medical Society; on the staff of the Orange County General Hospital; died in Las Vegas, Nev., September 14, aged 81, of coronary thrombosis.

Werner, Charles Henry ⊕ St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1906; an Associate Fellow of the American Medical Association; served during World War I; affiliated with Missouri Methodist Hospital and St. Joseph Hospital; for many years physician for the Welfare Board; died in the Veterans Administration Center, Wadsworth, September 17, aged 71, of thrombotic infarction with gangrene of the left leg.

Wolfort, Benjamin Edgar, Brooklyn; Johns Hopkins University School of Medicine, Baltimore, 1906; member of the American Academy of Orthopaedic Surgeons and the American Medical Association; affiliated with Jewish Hospital; died in September, aged 70, of coronary occlusion.

Woodbury, Frank Taylor ⊕ Wakefield, Mass.; Harvard Medical School, Boston, 1896; past president of the Middlesex East District Medical Society; on the honorary staff of Melrose Hospital; for many years trustee of the public library; died September 16, aged 78, of coronary thrombosis.

Young, Robert, Hoopeston, Ill.; Columbia University College of Physicians and Surgeons, New York, 1949; certified by the National Board of Medical Examiners; interned at Indiana University Medical Center in Indianapolis; intern in pediatrics at the University of Chicago Clinics in Chicago; served during World War II; died in Bob Roberts Hospital in Chicago, September 25, aged 25, of coronary occlusion.

FOREIGN LETTERS

LONDON

(From a Regular Correspondent)

Oct. 10, 1950.

Annual Representative Meeting, 1950

The meeting was held in the Great Hall of British Medical Association House, London, on Thursday, Sept. 28. The chair was taken by Dr. J. A. Brown (Birmingham), chairman of the representative body, who was supported by the president of the association (Sir Henry Cohen), the chairman of the Council (Dr. E. A. Gregg) and the treasurer (Mr. A. M. A. Moore). The meeting began at 9:30 a. m. and completed its work at 6.15 p. m.

The General Practitioner-Specialist.—Dr. Leak, on behalf of Mid-Cheshire, further moved: "That this meeting considers that greater recognition should be given to the established practitioner with specialist experience, who seems strangely neglected in the Council's recommendations on general practitioners and hospital work." He said that those concerned felt very keenly having to give up their specialist jobs after many years. They might not have the F.R.C.S. but they were persons with excellent records and experience and trusted by their patients, having lived for a long period with their successes and their failures. Mr. Staveley Gough said that he felt again that the wording of this motion showed lack of understanding of the report. At least three sections of the report were concerned with the introduction of the general practitioner in a specialist capacity into the hospital system. The boards of the hospitals had a public duty to see that the members of the staffs held certain qualifications or had had certain experience as assessed by committees of their brethren or by tests in open competition following public advertisement. Thus any general practitioner having the necessary experience and qualifications could answer a public advertisement for a post, and if he were a good man he would get the job. It had been realized that in the past there was an implication that he might not get the job because he was a general practitioner, but the report specifically stated that the fact of being a general practitioner would not bar him. Mr. Lawrence Abel (Marylebone) moved an amendment to end the motion at the words "specialist experience," omitting the denigratory reference to the Council's recommendations. The report covered these established practitioners and declared that the appointment of the general practitioner specialist should be retained and encouraged. This was bound up with the grading question. He said the grading would be examined in 1951. Many men had suffered three years' diminution of income because they had been incorrectly graded. The motion was amended and carried.

Designations of General Practitioners in Hospitals.—Dr. A. G. Heron (Bristol) moved: "That the Council be requested to provide a clear designation for general practitioners engaged (*a*) in paid sessional work in hospitals and (*b*) in honorary appointments for educational purposes, and shall endeavour to procure the acceptance of these designations by the regions, and that safeguards be set up so that a general practitioner attending a hospital as a clinical assistant for educational purposes shall not be used to fill an otherwise remunerable employment." He said that the Council had laid down as a principle that the term "clinical assistant" should be used only in its strictest sense. In the planning of action later in the report a dangerous ambiguity appeared to creep in. If these appointments involved useful work in hospital, such work should be paid for, even though it had educational value. Why should the underpaid general practitioner be the only member of the profession still required to work on an honorary basis? What hope had the general practitioner anesthetist, for instance, of achieving consultant status, with the queue of senior registrars and registrars awaiting appointments?

Mr. Staveley Gough said that the committee had approached this matter with some care. The term "clinical assistant" had in the past generally been associated with an honorary job. The first part of the committee's work was concerned with the endeavour to get hospital accommodation for the general practitioner. It was stated most specifically that a post created for educational purposes must be purely educational and carry no degree of clinical responsibility toward the patient. If the clinical assistantship carried with it clinical responsibility, this must be paid for. With regard to part time appointments, the committee was satisfied that such appointments should be paid ones. Dr. Watney Roe supported the motion. The solution was the early institution in hospitals and clinics of paid posts open to general practitioners. Dr. Heron said that Mr. Staveley Gough seemed to come dangerously near accepting the principle of sweated labor in order to get general practitioners into hospitals. The committee, he said, had not faced the question: When is a clinical assistant not a clinical assistant, and when he is not, what is he? The Bristol motion was carried.

The General Practitioner and Major Surgery.—Dr. A. C. E. Breach (Bromley) moved that there should be omitted from the council's interim report the statement ". . . it is stressed that major surgery should not be included in it," that is, the scope of general practice, and the further statement under the heading "Way in Which Integration May Be Achieved."

The motion read that he (the general practitioner) should, of course, not undertake major surgery. He must restrict himself to such work as is within his sphere. Major surgery should not be performed in general practice hospitals, although, of course, even in the smallest hospital this may be necessary in an emergency. He said that they were impressed by the over-all excellence of this report. Bromley was requesting not a positive assertion of the right of the general practitioner to practice major surgery but the deletion of a prohibition. They felt that, if that prohibition were allowed to go through unchallenged, it would come to be regarded as part of the policy of the association, that is, that a general practitioner, unless recognized by some other standards, such as assessment by selection boards, was not *ipso facto* entitled to practice the art in which he had qualified. If they once accepted the idea, there was no limit to the number of restrictions that could be imposed under the Medical Acts. It was intolerable that any committee, whether governmental or of their own profession, should say that a man who had achieved qualification as a surgeon must not practice surgery unless he had satisfied some extraneous board.

Mr. Staveley Gough begged the meeting not to be persuaded by an emotional approach to their rights as members of the profession. They were public servants. They had a responsibility to their patients and to their profession. The purpose of this report was to get general practice beds back and new wards open to the general practitioner. He went on to say that there were two sections of general practitioners: those who did general practice only, and those who also did, and had a right to do, specialty work outside general practice. The bodies responsible for hospitals had a right, if asked for general practice beds, to insure their being used for general practitioner purposes. The general practitioner-specialists had other possibilities of entering a hospital, but he must be prepared to show that he had the necessary special experience.

Dr. C. F. Mayne (Plymouth) supported all that Mr. Gough had said. He had spent 10 years in general practice before becoming a specialist, during which time he was on the staff of a hospital as a general practitioner. There must be safeguards for the patient, and he thought those safeguards were provided by the present report. It was wrong for general practitioner-surgeons to attack malignant disease in a small rural hospital when they were not in full collaboration with the radiotherapist of the area. The amendment in his view would have the effect of deleting certain safeguards that were in the patient's interests.

Lord Horder (Marylebone) thought that the words which Bromley wanted deleted were unfortunate. Care, he said, must be taken not to lay down limits, whether it be to the practice of medicine, surgery or midwifery. He did not mean by this that any general practitioner, however good he might be, should deal with a difficult and complicated surgical procedure for advanced cancer. That would be a travesty of common sense. But he thought it unfortunate that the word "must" came in ("He must keep to such work as is within his sphere"). A short time ago they were threatened with a veto on attending a woman for the delivery of her baby unless they had some special qualification or sanction to do so. They must notice how near they were standing to the sabotage of their own privileges. The Bromley amendment after some further discussion by several other speakers was carried by a large majority, and the interim report as amended was approved.

Women in Medicine

In a recent article in the *British Medical Journal,* there appeared a review of the proportionate numbers of women in London medical schools. The article points out that, whether or not one agrees with Sir Robert Hutchison's views that women in men's medical schools are a disturbing element, it is a fact that all the London medical schools are now coeducational. In 1944 the Goodenough Committee drew attention to the difficulties besetting women undergraduates who desired to study medicine in London. Coeducation was a familiar feature in medical schools in the rest of Britain. In London at the time of the report nine out of 15 medical schools of London University admitted men students only. There was one, the Royal Free Hospital Medical School, limited to women only. The committee considered that, in the interests of the public and of the medical profession, coeducation should become the practice in every medical school. They recommended a reasonable proportion of women students to men students in every school. The London University about that time said that its policy was to open all medical schools to men and women on terms of equal opportunity. The University Grants Committee bluntly said, "No coeducation, no grant." By 1947, all medical schools of London University were coeducational.

The proportion of women to men in Britain in 1938-1939 was 1 to 5.7. The provincial, Scottish and Welsh universities account for 1,275 out of 1,930 women medical students. This showed a "reasonable" proportion to be one woman to four men. But in the London University no fewer than 357 of the 551 women medical students were at the London School of Medicine for Women, that is, the Royal Free Hospital Medical School. The remaining 194 were in King's College, King's College Hospital, Queen Mary College, University College and University College Hospital. Figures for London as a whole showed that there was one female to every eight male medical students. In the Scottish extramural schools there was one woman to every 19 men, but these schools are exceptional—in 1938-1939, 40 per cent of the Scottish extramural students were from foreign countries.

By 1948-1949 the total number of women medical students had risen to 2,931. There was a fall in the men students to 10,281 (from 11,037). By that year the proportion of women students to men had risen to 1 : 3.5, representing an increase of 50 per cent over the figure for 1938-1939 (1 : 5.7). In Scotland and Wales and the provinces there was nearly one woman student to every three men, while in London the proportion of women (18.9 per cent) was close to the 1 : 4 proposed by the Goodenough Committee. Against this it must be recorded that the West London Hospital for Women in 1948-1949 had 68 women, but it has now ceased to recruit undergraduate students since it is to be converted to a school for postgraduate training.

Schools that were coeducational before the war continued to train about the same number of women students. King's College and King's College Hospital averaged 1 : 5.7 in 1948-1949; University College and University College Hospital show a slightly higher proportion of women (1 : 4.7); at Queen Mary College the figure is a little less (1 : 9). Of the nine schools that refused to take women before the war, none have as yet reached the Goodenough "reasonable" proportion of women to men. St. Bartholomew's, Charing Cross and St. George's hospitals come nearest, with one woman to every seven men. Guy's, London and Westminster have a proportion of less than 1 : 19. Intermediate between these come the Middlesex, St Mary's and St. Thomas's hospitals. When the Royal Free Hospital is included, the total proportion of female to male medical students at London University in 1948-1949 falls just short of the 1 : 4 recommended in the Goodenough report. If every school had its recommended reasonable proportion of women there would be 479 more women medical students in London than there are at present. However, extra facilities would have to be provided, and there would be fewer places for men, the article states, and this might lead to the reflection on the doubtful wisdom of trying to spread the load too widely. Feminists, they point out, should take note of the fact that the Royal Free Hospital, also coeducational, last year had the very unreasonable proportion of only one man to every 93 women medical students.

Victory Medal for Diabetes

Dr. Elliott P. Joslin, who celebrated his eighty-first birthday last June, is known throughout the world as a distinguished veteran in the fight against diabetes. About two years ago, as part of his effort to educate diabetic patients in healthy living and show them what proper care can do, he originated the Victory Medal, to be presented to every person who is still free of all vascular disease after a quarter-century or more with proved diabetes. In the 24 months up to June 1, 1950, 20 patients had passed this test. Last year Dr. Joslin gave a medal to Dr. R. D. Lawrence, who for 20 years had led an active professional life as a consultant in diabetes and is said to have been one of the first persons in Britain to receive insulin.

The above report appeared in a recent edition of the *British Medical Journal.* Dr. Howard F. Root has now invited its editor to award a bronze Victory Medal in Britain. The journal records its warm appreciation of the generous gesture of goodwill from our American colleagues. The medal is now in the office of the journal. A committee is to be formed to decide how best to award it. The medal, illustrated in Dr. Root's letter, was designed by Amelia Peabody. It is 2 inches in width, and on the reverse side appear the words "For life and health through perseverance and scientific medicine."

ISRAEL

(From a Regular Correspondent)

JERUSALEM, Nov. 9, 1950.

Dracunculosis Among Immigrants from Yemen

During the past year there has been an incidence of tropical diseases which had not been previously observed in Israel. I. Katzenellenbogen has published his first observation of cases of dracunculosis in *Harefuah* (Oct. 15, 1950). The patients were between 3 and 67 years of age. Of the 49 patients, who had arrived in Israel eight months previously, four came from Sharab and 45 from Suda, a large village in the marshes of Yemen. All the patients except those from Sharab had had numerous filariae in the past as well as during the observation period in Israel, which occurred in the summer months. Filariae were not seen during the past winter.

Swelling, inflammation of the limbs, boils and blisters of the skin, rise of temperature and general malaise preceded the appearance of the worms. While the feet and legs were predominantly affected, filariae were also seen extruding from the buttocks, mammae, palms and even the penis. Seventeen worms were observed in a 5 year old boy during his seven week stay in the hospital. Cellulitis-like swellings and blisters with rise of temperature up to 40 C. (104 F.) would occasionally announce the arrival of a new Dracunculus. Occasionally filariae protruded from under tiny scabs with practically no inflammation and no rise of temperature. The period of time from the perforation of the skin and the appearance of the embryos containing pus to the emergence of the worms varied, even in the same patient, from a few days to two or three weeks.

In three patients calcification of dead filariae from previous attacks was noted. Large pigmented scars on the legs and buttocks were found in patients with earlier attacks of dracunculosis. In practically all adult patients the worms recurred regularly every year. One patient was reported to have had more than 300 filariae in the past. The results of blood cell counts were not uniform. Leukocytosis and eosinophilia were noted in some patients. A child with numerous filariae had a normal eosinophil count but a leukocyte count of 19,000 and hemoglobin of 68 per cent. Treatment was completely symptomatic. Penicillin and sulfonamides were given in cases of cellulitis and similar septic inflammations.

First Research Council Bulletin

The Research Council of Israel, attached to the Prime Minister's Office, has issued its first bulletin. The Council's task, as defined by Mr. Ben Gurion at its first meeting, is threefold: (1) to foster pure and applied research and to coordinate scientific and higher educational activities in the interest of the development of the country and the absorption of immigrants, (2) to improve scientific equipment in general and to establish laboratories for physics and biology and (3) to assist young research workers and to invite experts from abroad. The bulletin surveys the tasks and present activities of the five principal committees and their subcommittees, dealing with fundamental research questions, industrial research, building problems, food and agriculture. The practical importance of this kind of research is illustrated, for instance, by the fact that the damage caused by corrosion of irrigation pipes amounts to at least one million pounds yearly.

Donation to Medical School

Through the efforts of Prof. J. M. Rogoff, of the University of Pittsburgh, United States, $25,000 has been donated for the equipment of a physiology laboratory for the University-Hadassah Hospital Medical School. Professor Rogoff was also instrumental in obtaining through the Phi Lambda Kappa Fraternity of Jewish physicians in the United States four annual scholarships, each valued at $1,500, for students of the medical school. Professor Rogoff gave the first series of lectures to the first class of medical students after the formal opening of the medical school in May last year.

BRAZIL

(From a Regular Correspondent)

RIO DE JANEIRO, Sept. 28, 1950.

Identification of Leptospirae in Rats

Dr. V. O. Guida, of the São Paulo Biological Institute, studied serologically 29 strains of leptospirae isolated from Rattus norvegicus captured in the city of São Paulo and ascertained, through agglutination and lysis, the titers of the serums from infected and noninfected rats and their relation to infection in those rodents. The 29 strains of leptospirae could all be identified as Leptospira icterohemorrhagiae, as they reacted positively with anti-icterohemorrhagiae serum and negatively with anticanicola serum. In 16 strains the levels of antibodies were as high as 1:15,000. The search for antibodies against L. icterohemorrhagiae in 24 rats from the same city was positive (1:50) in 11 out of 17 adult animals and negative in seven young ones. The search for Leptospira in the kidneys of 11 positive animals by the combined methods of dark field, culture and Guinea pig inoculation was successful in 9 cases. The other two rats, despite a high serologic titer (1:300 and 1:15,000) were not Leptospira carriers and were probably in a recent self-sterilizing stage.

Intrauterine Transmission of Schizotrypanum Cruzi Disproved

The common mechanism of transmission of the causative agent of American trypanosomiasis (Chagas' disease) from vertebrate to vertebrate is by means of intermediate hosts, i. e., the cone-nosed bugs of the family Triatomidae. Direct passage from a female animal to her young has also been observed. The congenital transmission in man, although considered by Chagas to be the principal cause of the chronic nervous form of trypanosomiasis, has not yet been proved. Dr. J. Pedreira de Freitas and Dr. Francisco Pinto Lima, of the Department of Parasitology, University of São Paulo, have recently reported a case of a woman, ill with Chagas' disease, who died at the end of pregnancy and whose child, also dead, was not infected. The clinical and pathological pictures of the mother revealed an intense chronic myocarditis, the etiology of which was made clear by positive complement fixation reaction and xenodiagnosis. Pathological examination of the fetus did not reveal any change that could prove the presence of the infection, nor did the placenta show any nest of the Leishmania stage of the trypanosoma, as is so frequently observed in animals infected with the parasite.

Concurrent BCG Vaccination and Familial Tuberculosis

Dr. Arlindo de Assis published a paper adding factual evidence that concurrent BCG vaccination is, as he says, strikingly more efficient than the common immunization of newborn infants. Both procedures are used as a means of fighting child tuberculosis in Rio de Janeiro. Dr. Assis reported the instance of a poor couple who had had 12 children. The first seven had not been immunized with BCG, while the last five received the protection of the vaccination immediately after birth. Of the seven nonvaccinated children, four died in early infancy, of diseases described by the parents as meningitis and capillary bronchitis. The three living nonvaccinated children are healthy and react to tuberculin. In the last few years, the father began to present symptoms of a disease described as chronic bronchitis but which was later found to be pulmonary tuberculosis. From then on the couple agreed to have their newborn children vaccinated with BCG, four of them having been immunized immediately after birth by the Calmette method, the last one by the concurrent method (six BCG doses during the first semester of life). Of the four immunized by the Calmette method, two died of capillary bronchitis and acute bronchopneumonia. The other two children presented radiological and allergic pictures of primary active tuberculosis, in one of them confirmed by guinea pig inoculation of gastric material. Both children continue to react to tuberculin. The last child, born during the undisputably bacilliferous stage of the father's illness, in direct contact with the father to the age of 4½ months, when the father died. This last child, a boy, vaccinated by the concurrent method, was entirely free from the effects of the contagion and is now 54 months old. Since the age of 16 months he has not reacted to tuberculin (anallergy up to 10 mg. of unpurified tuberculin).

Chronaxia, Curare and Neostigmine in Man

Drs. J. Souza Campos and Elvio Fuser, of the N. S. Aparecida Hospital of Rio de Janeiro, reported their study on chronaxia with frogs and human patients under the effect of curare and neostigmine. Patients who received therapeutic doses of curare never presented changes of the normal values of chronaxia. Some showed advanced symptoms of curarization (paralysis of the abdominal limbs, difficulty in swallowing, slight cyanosis), which led to the use of the antagonistic drug (neostigmine). Even then the values of chronaxia were normal. Under experimental conditions with toxic doses, after the appearance of neuromuscular dysfunction, an increase of 10 and 12 times the normal value was always observed, but the chronaxia of the nerves was normal. Human patients treated with neostigmine did not show any chronaximetric changes in muscles and nerves, and in frogs paralyzed by neostigmine the chronaxia of muscles and nerves was also normal. In these animals, neostigmine did not reduce the high values characteristic of curare poisoning. In conclusion, the systematic increase of the chronaxia value in frogs under curare intoxication is observed only after the appearance of neuromuscular dysfunction (Claude Bernard's phenomenon).

COLOMBIA

(From a Regular Correspondent)

Bogotá, Oct. 4, 1950.

Early History of Cinchona

Prof. Jaime Jaramillo Arango, former rector of the National Faculty of Medicine and former Colombian ambassador to England, recently published an article in *Revista de la Facultad de Ciencias Médicas of Quito* (April 1950) entitled "Critical Study of the Basic Facts of the History of Cinchona." This study has also appeared in the *Review of the Linnean Society of London; Revista de la Academia de Ciencias Exactas, Fisicas y Naturales* (Madrid) and *Anales de la Sociedad Peruaña de la Historia de la Medicina.* Professor Arango's work has been commented on in the *Review of the New York Botanical Gardens* by F. R. Fosberg, who considers the study to be the "last word on the early history of cinchona." Dr. Jaramillo Arango believes that the American Indians knew about and used the bark of the cinchona tree. There is no definite evidence concerning the first use of cinchona bark by the Europeans. The legend of the cure, whether of the Countess or of the Count of Chinchon, is almost completely refuted. The theory that the Jesuits first introduced quinine to Europe and were responsible for its extensive use there is the most plausible one. They apparently brought the drug to Rome during an epidemic of malaria, which they controlled with quinine. Possibly before this, others may have brought it to Spain. The oldest work on quinine seems to be the "Schedula Romana" of 1649, attributed to Puccerini. Professor Arango discusses the classification of the cinchona by Linnaeus, the discovery of quinine by Mutis in Nueva Granada and the basic change in the genus of cinchona, from the original C. officinalis to C. cardifolia (C. pubescens), in the twelfth edition of the "Systema Naturae" (1767).

Therapeutic Tests with Antireticular Cytotoxic Serum in Schizophrenia and Arteriosclerotic Dementia

Dr. Carlos Artega Camero published in the *Revista de la Facultad de Medicina* of Bogotá (June 1, 1950) the results obtained with antireticular cytotoxic serum in 30 patients in the Women's Mental Hospital of Bogotá. Twenty-four had schizophrenia of long duration and had been previously subjected to various shock treatments without improvement: five had senile dementia with cerebral arteriosclerosis, and one had an exogenic puerperal psychopathy. A permanent remission of mental illness was obtained in only the last-mentioned patient. There was no improvement in 12 schizophrenic patients, while improvement was transient in six and permanent in six. None improved to a degree that would have allowed her to return home and become reintegrated again in normal family life. Of the five patients with senile dementia and cerebral arteriosclerosis, two showed no improvement, two permanent improvement and one died on the fifth day after the termination of the treatment owing to an intercurrent disease. The author concludes that Bogomolest's serum is of some value in schizophrenia. It is of promissory value in senile dementia, cerebral arteriosclerosis and exogenic infectious psychosis, but the limited number of cases observed does not permit definite conclusions. The author's results do not agree with those reported by others.

New Faculty of Medicine

The new Faculty of Medicine of the University of Cauca in Popayan City began functioning on October 2. Under the jurisdiction of the National University it will have the same programs and standards of the university. The school opened with 70 students and the following staff: Dr. Nestor Santacoloma, dean and professor of anatomy; Dr. Alvaro Angulo, assistant professor of anatomy; Dr. Leonardo Santamaria, professor of medical chemistry; Dr. Julio Cesar Perafan Fajardo, professor of medical physics, and Dr. Reinaldo Coronel, professor of medical drawings. Only first year medicine is to be presented this year. The curriculum will be expanded so that the students will be able to complete their studies. The present school is a reestablishment of the old school that was in operation in Popayan City during the nineteenth century. The Faculty of Medicine of the University of Cauca was established on Aug. 5, 1835 and was in existence until 1890.

Lectures

Dr. Eduardo Coke, former minister of public health and professor at the University of Santiago, Chile, visited Bogotá in August. He spoke at the National Academy of Medicine and at the Colombian Medical Federation on the pathogenesis of cancer and on the establishment of social security in Chile.

Dr. Vicente Senti Montagut of the Faculty of Medicine and of the Provincial Hospital of Madrid, Spain, lectured at the Facultad de Medicina of the National University, Sept. 11, on the pathogenesis and treatment of scoliosis.

Drs. Herald R. Cox and Sydney H. Babcock Jr., of the United States, were invited to lecture at the National University and the Javeriana University. They remained in Bogotá from September 19 to 25. Dr. Cox, winner of the Theobald Smith Award of 1941, spoke on experiments on neurotropic virus as oncolytics and on aureomycin therapy in rickettsial diseases. Dr. Babcock spoke on antibiotics in general.

CORRESPONDENCE

TREATMENT OF POSTANESTHESIA NAUSEA AND VOMITING

To the Editor:—Since the introduction of dimenhydrinate (dramamine®) in 1947 by G. D. Searle & Co. many uses have been found for this drug. The most phenomenal results were those in motion sickness published by Gay and Carliner. Nevertheless, its major usefulness will be evaluated differently, depending on the phase of medicine in which one is interested. This is well illustrated by the following reports: (*a*) E. F. Kerman successfully treated 15 patients for nausea following electric shock and also eight patients with migraine, (*b*) E. Brentan employed it in migraine, (*c*) Beeler and co-workers in radiation sickness, (*d*) Campbell after fenestration operations and (*e*) Stoecker after local anesthesia in ophthalmology. All reports show good results. However, one of the most important uses of dimenhydrinate has not been reported as yet: that is, its use for nausea and vomiting following general anesthesia.

In ophthalmology it is imperative that the patient should not vomit after intraocular surgery or diathermy for detachment of the retina. While the need for maintaining the patient in a quiescent state after surgery may not be so acute in other specialties, the well-being of any surgeon's patient is always a prime requisite.

The possibilities of dimenhydrinate in postanesthesia vomiting first occurred to me in December 1949, while interrogating a patient who had recently lost an eye because of vomiting following a cataract extraction. The patient had previously had two operations with intravenously administered thiopental sodium as an anesthetic. He had been so delighted with this form of anesthesia that, when he was ready for the cataract operation, he requested its use for this operation. After its use, he vomited severely for eight consecutive days. No remedies were of appreciable benefit. As morphine had been given for this third operation, in spite of orders to the contrary, it was thought that this may have been the offending agent. Consequently, when a fourth operation was under consideration, the patient, the anesthetist and the surgeon discussed the type of anesthesia to be employed. As the patient was apprehensive, he again decided on thiopental sodium without morphine.

After the fourth operation he was very sick—he was nauseous and vomited. The night of the operation the patient was found lying on his abdomen holding onto the bed. When he said his head was going around so that he felt he must "hold on for dear life," the use of dimenhydrinate was immediately thought of. The anesthetist had not previously employed it for this purpose. However, he administered 100 mg. rectally. In approximately a half-hour the patient had entirely recovered. Since that time we have employed dimenhydrinate as a preoperative prophylactic measure, with considerable satisfaction.

The departments of anesthesiology of both local hospitals have availed themselves of this information. The staff of the St. Joseph Hospital has employed the drug in 16 cases for postanesthesia nausea and vomiting, from ether in three cases, thiopental sodium in 10 and cyclopropane in three. The results in all cases were excellent. The staff at Memorial Hospital has used it with good results in six cases in which cyclopropane anesthesia had been used.

The present lack of knowledge of the total pharmacologic action of dimenhydrinate precludes the possibility of analysis of its therapeutic effect. The cases in which we used it certainly suggests a quieting effect on the labyrinth. It is our impression that in these patients a toxic labyrinthitis develops from the high concentration of the anesthetic agent in the blood stream during anesthesia. The sedative action of dimenhydrinate in motion sickness also embraces this impression.

The dosage employed prophylactically was 100 mg. given orally a half-hour before operation. In cases in which nausea and vomiting followed surgery (no dimenhydrinate having been given before surgery) 100 mg. were suspended in 20 cc. of isotonic sodium chloride solution and given rectally.

ANTIDOTES FOR BROMATE NEUTRALIZERS

To the Editor:—In view of the recent editorial comment (Neutralizers in Home Permanent Waving Kits, *J. A. M. A.* 144:397 [Sept. 30] 1950) on neutralizers in home permanent waving kits, publication of a standard antidotal procedure for accidentally ingested bromate neutralizer may be of some value.

1. Administration of an emetic.
    - (*a*) Mustard powder, 1 teaspoonful, in 300 cc. of warm (not hot) water, or
    - (*b*) Zinc sulfate, 1 teaspoonful, in water, followed by copious ingestion of water, or
    - (*c*) Apomorphine, 5 mg., intramuscularly.
    - (*d*) Gastric lavage.
2. Sodium thiosulfate, 1 level teaspoonful in water. This may precede but should in addition always follow the emetic.
3. Demulcent drinks, such as milk, flour and water or cereal gruel.
4. Sodium thiosulfate solution, 1 per cent by intravenous drip, in quantities of 100 to 500 cc. If not feasible, 10 to 50 cc. of 10 per cent solution of sodium thiosulfate may be given intravenously.

Gastric washings and urine should be tested for the presence of bromide. Since a fatal outcome is apparently dependent on the nephrotoxic effect of bromate, speedy removal of the material from the stomach by mechanical or chemical means is of the utmost importance. When uremic symptoms develop, treatment is indicated as for mercury poisoning, since tubular degeneration similar to that produced by mercury has been noted in bromate studies on animals.

It should be noted that the antidotal procedure listed above is not applicable for all cold wave neutralizers. In the past year, one manufacturer (The Toni Company), cognizant of the toxic properties of bromate, has discontinued its use and has been supplying in its stead a neutralizer consisting of sodium perborate and sodium hexametaphosphate. Toxicological studies of this new formulation had shown it to be of considerably lower toxicity than bromate, since all experimental animals survived administration of relatively large quantities (exceeding, on the basis of body weight, the "human dose"). When antidotal procedures are required in a case of perborate ingestion, those listed under heading 1 may be used. In addition, the administration of magnesium sulfate by mouth is suggested.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Chiropractic Practice Acts: Revocation of License for Fraud and Deception.

The plaintiff, a chiropractor, filed an action to annul an order of the defendant, the State Board of Chiropractic Examiners, which revoked his license to practice chiropractic. From a decree sustaining the revocation order, the plaintiff appealed to the court of appeals of Tennessee.

The evidence showed that the plaintiff, who was licensed to practice chiropractic but possessed no license to practice medicine, had practiced medicine and surgery on two persons during 1947 and 1948 on specified occasions. The acts which were found to have constituted the practice of medicine were the use of hypodermic injections, the prescribing of medicines and the performance of an operation for the removal of a vaginal tumor. It is not claimed that his activities were authorized by his license as a chiropractor under the statutes defining the art as "the science of palpitating, analyzing and adjusting the articulations of the human spinal column by hand." It is insisted, however, that the chiropractic act is definitive and not prohibitive and that, since the act does not expressly prohibit any of the activities in which the plaintiff engaged, the defendant exceeded its authority and acted illegally in revoking the plaintiff's license. In brief, it is argued that the defendant assumed a legislative prerogative by creating on its own initiative and authority a ground for revocation and that its action in so doing destroyed a property right in violation of the constitutions of both the state of Tennessee and of the United States.

The right to practice a lawful profession, said the court of appeals, is a property right of which one cannot be illegally deprived. A license to practice a profession affecting the welfare of the public and, therefore, subject to the police power of the state, however, is not a contract entitling the holder to continue the practice of his profession unrestricted and unregulated. The state legislature unquestionably has the right, in the exercise of its police power, to set up boards to investigate the practice of the professions and to endow such boards with the right and duty to revoke, for good cause, a license previously granted. The power so delegated, however, can involve only a discretion as to when a proper occasion exists for executing the power. It cannot extend to the making of a new law. To avoid a violation of this principle, we think it must be said that the revocation of a license to practice a lawful profession cannot be predicated on acts or conduct not specified in the statute or embraced within its general terms.

Continuing, the court said that this does not mean, however, that in addition to providing specific grounds for revocation such boards may not validly be granted the power to revoke on general grounds which, by common understanding and universally accepted standards, are regarded as dishonorable, disreputable or incompatible with the honest practice of the licensed profession and the public welfare. For example, charges involving such general grounds as "unprofessional," "dishonorable" or "immoral" conduct and words of like general import in connection with the practice of the profession of medicine are frequently made the predicate for revocation of a license to practice that profession. We think the legislature, after laying down specific grounds for the guidance of the defendant, intended by the chiropractic act also to confer on it the power to revoke the license of a chiropractor whose activities were found to be unprofessional or subversive of the public interest and welfare. It did so, in our opinion, by authorizing the board to revoke the license of a practitioner who "in any way" has been "guilty of deception or fraud in the practice of chiropractic." This language, while confined to activities occurring in connection with the practice of the profession of chiropractic, is general in scope and meaning. Can it be supposed that one who, under his license as a practitioner of chiropractic, purports to engage in the practice of medicine and even of surgery, as shown in this case, and exacts a fee for such "services," has not been guilty of "deception and fraud in the practice of chiropractic?" The legislature with good reason has gone to great pains to define the standards for practitioners of medicine and has said that those who meet the standards of that profession can practice it. This clearly implies that others cannot. The plaintiff, by the undisputed evidence, has violated this policy.

When a licensed practitioner in one field uses his license in another field, and the title of "Doctor," to engage in an illegal practice, it is easy to see how the ignorant and credulous could be induced to part with their money on a false assumption. We think the conclusion that such conduct amounts to a fraud and a deception in the practice of the art for which a license has been issued is inescapable. In our view the language of the act under consideration is no more subject to attack as being too general than if it has used the language "unprofessional," "disreputable" or "immoral." Fraudulent or deceptive conduct in connection with the practice of a profession must be held to be unprofessional, disreputable and immoral. In practical effect, the terms are synonymous. Accordingly the order and decree revoking the plaintiff's license to practice chiropractic was affirmed.—*Janeway v. State Board of Chiropractic Examiners et al., 231 S.W. (2d) 584 (1950).*

Medical Motion Pictures

Behind the Menu. 16 mm., black and white, sound, showing time 10 minutes. Produced in 1950 by the National Film Board of Canada for the Department of Health and Welfare. Procurable on rental or purchase from National Film Board of Canada, 400 West Madison Street, Chicago 6, and 1270 Avenue of the Americas, New York 20.

This motion picture depicts a warning against unsanitary conditions in restaurants and demonstrates precautions that should be taken against dirt and harmful bacteria in the handling of food. Suggestions are made for increasing efficiency through better food storage, dishwashing methods and staff facilities. A few measures taken by public health authorities to maintain standards of restaurant sanitation are also portrayed.

The film points out some of the bad practices in the preparation and handling of food and the treatment of the refuse that spreads communicable diseases, emphasizing the proper as well as the improper methods of handling food, equipment and utensils. In a clearcut way, it points out most of the procedures that are essential in the control of spread of disease. A few of the protective measures taken by many restaurant owners which are illustrated are provision of easily cleaned equipment, arrangements for adequate staff washing facilities and spraying of kitchens with insecticides. Proper dishwashing methods are demonstrated, and a magnified picture of the bacteria lurking on poorly washed dishes proves the need for sterilization. Scenes in a dirty restaurant point up the danger signals by which customers can recognize poor places to eat: flies, chipped crockery and lipstick on the drinking glasses. Visits of inspection and routine tests by public health authorities are described. One sequence portrays a couple going into an unsanitary restaurant. The narrator suggests that the only effective means of raising health standards in restaurants is by the refusal of customers to patronize those where insufficient sanitary precautions are taken. However, this is ineffective from a production standpoint since the couple does not make any attempt to carry out the suggestions of the narrator.

The film is made in such a way that it would appeal to both professional and nonprofessional persons, and even those with no concept of food handling would benefit from seeing the picture. It is a good introductory film to the subject of food handling and should be shown to public health workers, service clubs, high school students, PTA groups and other organizations concerned with improving local restaurant conditions. The photography and narration are good.

POSTGRADUATE CONTINUATION COURSES FOR PHYSICIANS

	SURGERY—Continued		
Harvard Medical School Courses for Graduates, 25 Shattuck St., Boston, Mass. At: Massachusetts General Hospital	Experimental and Clinical Surgery	Arranged, 6-12 months, full time	$800.00[1] for 12 months
Tufts College Medical School, 30 Bennet St., Boston 11, Mass.	Principles of Surgical Technique	May 21-June 29, 6 weeks, part time	250.00[1]
Wayne University College of Medicine, 1512 St. Antoine St., Detroit, Mich.	Surgery Seminar	January and April, 12 weeks, part time	15.00
University of Minnesota Center for Continuation Study, Minneapolis 14, Minn.	Surgery for General Physicians	May 17-19, 3 days, full time	20.00
Essex County Medical Society, Newark, N. J. At: Newark City Hospital	Surgery of the Autonomic Nervous System	February 16, 8 sessions, part time	100.00
Columbia University, 630 W. 168th St., New York At: Several Affiliated Hospitals	Surgery PM 100 Recent Developments in Surgery	May 14-18, full time	50.00
New York Medical College, Flower and Fifth Ave. Hospitals, 20 E. 106th St., New York, N. Y.	Thoracic Surgery	Arranged, 3 weeks, full time	325.00
	Surgical Technique	Arranged—50 hours	375.00
	Combined Surgical Course	January and April, 3 months, full time	350.00
New York Polyclinic Medical School and Hospitals, 345 W. 50th St., New York 19	Clinical Surgery	January and April, 6 weeks, full time	100.00
	Clinical and Operative (Cadaver) Surgery	January and April, 6 weeks, full time	200.00
	Traumatic Surgery Including General Surgery, Orthopedic Surgery and Physical Medicine	Arranged, 2 months, part time	200.00
New York University Post Graduate Medical School, 477 First Ave., New York At: Bellevue and University Hospitals	661-B Review of General Surgery for Specialists	April 2-28, 4 weeks, full time	300.00
	662-A The Basic Problems in Cancer Therapy for Specialists	January 22-February 3, full time	200.00
	6813-A Surgery of the Hand	March 26-31, 6 days, full time	100.00
	6814-A Seminar in Traumatic Surgery	February 5-17, full time	150.00
	6815-A Surgery of Trauma	April 5-June 7, part time, 10 sessions	100.00
Joint Committee on Postgraduate Education, 1313 Bedford Ave., Brooklyn 16, N. Y.[14] At: St. John's Episcopal Hospital	Office Surgery	April, 8 sessions, part time	20.00
Cleveland Clinic and Bunts Educational Institute, Euclid Ave. at E. 93rd St., Cleveland, Ohio At: Cleveland Clinic	Elective Surgery of the Gastro-intestinal Tract	Spring, 2½ days	15.00
University of Oregon Medical School, 3181 S.W. Sam Jackson Park Rd., Portland 1	General Surgery	March 12-16, full time	50.00
	THERAPY		
University of Michigan Medical School, Dept. of Postgraduate Medicine, Ann Arbor, Mich. At: University Hospital	Recent Advances in Therapeutics	May 3-5, 3 days, full time	15.00
Joint Committee on Postgraduate Education, 1313 Bedford Ave., Brooklyn 16, N. Y.[14] At: Jewish Sanitarium and Hospital for Chronic Diseases	Clinical Therapeutics	April, 7½ weeks, part time	40.00
	UROLOGY		
College of Medical Evangelists, 312 N. Boyle Ave., Los Angeles 33, Calif.	General Urology	January 3-February 28, 9 weeks 9 sessions	35.00
University of California, University Extension, San Francisco 22, Calif. At: Franklin Hospital	Urology	March 26-29, full time	Not given
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago, Ill.	2 week intensive course in Urology	April 16, full time	225.00
State University of Iowa College of Medicine, Iowa City, Iowa	Urology for the General Practitioner	April, 1 day	5.00
New York University Post Graduate Medical School, 477 First Ave., New York At: Bellevue, University and Affiliated Hospitals	671-A Advanced Course in Urology (for Specialists)	February 5-March 31, full time	350.00
American Urological Association, South Central Section, 4105 Live Oak St., Dallas, Tex. At: Palm Garden, Adolphus Hotel, Dallas, Tex.	Postgraduate Urological Seminar[13]	January 29-February 2, full time	50.00
	VENEREAL DISEASES		
U. S. Public Health Service, Hot Springs National Park, Ark.	Venereal Disease PG Course	April 16-20, full time	None
Wayne University College of Medicine, 1512 St. Antoine St., Detroit, Mich. At: Social Hygiene Clinic, Detroit	Conference on Venereal Disease	Quarterly, 12 weeks, part time	15.00
University of Pennsylvania, Institute for the Study of Venereal Disease, Hygiene Bldg., Philadelphia 4	6 months Essential Basic Training Course	Arranged, 6 months, full time	Arranged
	4 weeks Intensive Review Course	Arranged, 4 weeks, full time	Arranged
	3 weeks Venereal Disease Review Course	Arranged, 3 weeks, full time	Arranged
	10 day Refresher Course in Venereal Disease Control	Arranged, 10 days, full time	Arranged

---

[1] $5.00 Registration fee.

[2] Stated 2 week period may be followed by additional studies at $100 per week. Course may also be taken by Philadelphia area physicians on 6 consecutive Thursdays, 36 hours at $150.00.

[3] Tentative

[4] $12 per week for short periods.

[5] $60.00 for 5 days.

[6] For 12 weeks. $175—8 weeks; $100—4 weeks.

[7] Advanced candidates-in-training only.

[8] Applications for 1951 class accepted now until March.

[9] 3 months $100.

[10] 3 months $150.

[11] 3 months $250.

[12] Plus $10 laboratory fee.

[13] Of especial value to candidates for American Board of Urology.

[14] Medical Society of the County of Kings, State University Medical Center at New York, College of Medicine.

[15] 2 weeks $110; 1 month $200; 2 months $300.

[16] Sponsored by University of Pittsburgh also.

[17] Sponsored by Milwaukee chapter American Academy of General Practice also.

[18] No charge for room and board.

[19] For 1 month; $250 for 3 months; $450 for 6 months; $650 for 9 months; $850 for 12 months.

[20] Restricted to physicians licensed to practice in N. Y. State.

CURRENT MEDICAL LITERATURE

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1939 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

220:237-356 (Sept.) 1950

Effect of Potassium and Electrocardiogram in Normal Dog and in Dogs with Myocardial Infarction. S. Bellet, P. C. Gazes and W. A. Steiger.—p. *237.*

Effect of Different Grades of Myocardial Infarction on Tolerance of Potassium: Experimental Study in Dogs. S. Bellet, W. A. Steiger and *P. C. Gazes.—p. 247.*

Bernheim's Syndrome Considered in Light of Fatal Case. E. B. Wilson and S. L. Zimmerman.—p. 257.

Sudden and Unexpected Natural Death: III. Spontaneous Subarachnoid Hemorrhage. M. Helpern and S. M. Babson.—p. 262.

*Sickle Cell Anemia in White Race: Study of Family with Review of Genetic Theories. R. A. Guyton, R. W. Heinle.—p. 272.

Subacute Erythremic Myelosis: Report of Case in Filipino. V. de la Fuente.—p. 276.

*Leukemia in Radiologists in 20 Year Period. H. C. March.—p. 282.

Adrenal Cortical Function in Essential Hypertension: Study of Sweat Sodium Concentration. S. Eisenberg, R. Buie Jr. and L. Tobian Jr. —p. 287.

Experience with Protein Bound Iodine (PBI): Effect of ACTH and Cortisone on *Thyroid Function. J. D. Hardy, C. Riegel* and E. P. Erisman.—p. 290.

Miliary Tuberculosis of Liver: Liver Biopsy as an Adjunct to Diagnosis. M. M. Mansuy and W. J. Seiferth.—p. 293.

Polarographic Studies of Proteins and Their Degradation Products: III. Polarographically Determined Protein Index in Arthritic and Other Diseases. O. H. Müller and J. S. Davis Jr.—p. 298.

Response to Metacholine in Rheumatoid Arthritis. G. A. Perera and C. M. Plotz.—p. 307.

Absence of Intrinsic Factor from Intestinal Juice of Patients Following Total Gastrectomy. M. Paulson, C. L. Conley and E. S. Gladsden. —p. 310.

Periarteritis Nodosa Simulating Eosinophilic Leukemia. Case Report. C. Blackburn.—p. 313.

Tissue Culture Techniques in Study of Animal Viruses. F. C. Robbins and J. F. Enders.—p. 316.

Epidemic Diarrhea of Newborn. J. E. Gordon and A. D. Rubinstein. —p. 339.

Sickle Cell Anemia in the White Race.—Guyton and Heinle report sickle cell anemia in a white Sicilian girl. The sickling trait was present in five of nine available members of her family. Several theories of the genetics of sickle cell anemia had been advanced, but none of these previously widely accepted theories fully explained the genetics in all reported cases. It is certain from individual and family study in reported cases that transmission as a simple mendelian dominant is an impossible explanation in many instances. The homozygous-heterozygous theory suggests that there is a gene in Negro populations which when heterozygous results in sicklemia and when homozygous results in sickle cell anemia, a situation analogous to that which exists in familial erythroblastic (Cooley's) anemia. This theory is probably correct, but failure of one or both parents of a sickle cell anemia patient to show sickling may be the result of incomplete penetrance of the trait-producing gene.

Leukemia in Radiologists.—According to March, the incidence of leukemia in United States physicians who are not radiologists for the five year period 1944-1948, inclusive, is 113 in 15,637 (0.72 per cent). The incidence of leukemia in radiologists during the same period is 6 in 124 (4.84 per cent). These percentages approximate those reported for the preceding 15 year period, 0.44 and 4.57 per cent, respectively. The combined figures for physicians for the two decades 1929 to 1948, inclusive, are as follows: 65,922 nonradiologists died, 334 of whom died of leukemia. During this same 20 year period, 299 radiologists died, 14 of whom had leukemia. The over-all incidence for nonradiologists is 0.51 per cent and for radiologists 4.68 per cent. It is thus seen that the incidence of leukemia in radiologists is more than nine times as great as in nonradiologists. This difference has statistical significance. It is suggested that the increased incidence of leukemia in physicians as a whole (compared with the adult male white population) might be due to the same factor of exposure to ionizing radiation.

Effect of Sodium Sulfadiazine on Renal Tubule (Nephron) of Albino Rat. J. G. Brunson and J. G. Edwards.—p. 923.

Observations on Mitotic Reaction Induced in Liver of Rats by Thiourea. M. Rachmilewitz, A. Rosin and L. Doljanski.—p. 937.

Importance of Methionine and Choline in Arrest of Dietary Cirrhosis of Liver in Rat. E. R. Jaffé, R. W. Wissler and E. P. Benditt.—p. 951.

Muscles and Nerves in Poliomyelitis.—Denst and Neuberger obtained muscles and nerves at autopsy from 12 patients with poliomyelitis. Five deaths occurred during the acute stage, from the third to seventh day after the onset of clinical symptoms. Three patients died from 16 to 60 days after the onset. Four patients who were chronically ill survived from 14 months to three years after the initial paralysis. Samples of the following muscles were taken: temporal, sternocleidomastoid, pectoralis major, deltoid, biceps brachii, intercostals, diaphragm, rectus abdominis, psoas, quadriceps femoris, adductor magnus and gastrocnemius. The nerves that were studied included the phrenic, intercostals, the three cords of the brachial plexus, femoral and sciatic. These muscles and nerves presented a characteristic histological picture independent of their location. Two additional cases of bulbar poliomyelitis, with a duration of two and seven days, respectively, were examined. The muscular changes consisted of early fatty metamorphosis, followed by varying degrees of degeneration, atrophy and late fibrosis. Plasmodial formations of sarcolemmal nuclei in connection with disintegration of muscle fibers were seen frequently. Hypertrophic fibers were found in late cases. Proof of true regeneration was lacking. The histological picture resembled as a rule, that of the neurogenic forms of muscular atrophy but occasionally was reminiscent of that of progressive muscular dystrophy. The nerves showed early stripe-like demyelination and relatively minor change in the axis cylinders. The lesions in the nerves appeared less severe and less extensive than those in the muscles. The pathological process appeared to be different from wallerian degeneration. The possibility of direct action of the virus on muscles and nerves must be considered.

Mediastinal Emphysema.—Evans and Smalldon report the occurrence of mediastinal emphysema in 50 patients. Pulmonary interstitial emphysema followed a prolonged and difficult combined abdominoperineal resection in two patients Mediastinal emphysema occurred as a complication during an asthmatic episode in four patients. The creation of a pressure gradient between alveolus and vessel sheath as the result of atelectasis of a portion of lung produced mediastinal emphysema in one patient. Ten cases of mediastinal emphysema occurred in patients in whom an obstruction to the airway, which necessitated tracheotomy, was the precipitating factor. Mediastinal emphysema developed after diagnostic puncture of the external jugular vein in two patients There were six cases of mediastinal emphysema in full term newborn babies, with four deaths. Spontaneous mediastinal emphysema arose without apparent cause in three presumably healthy persons in whom no underlying pathological condition was subsequently demonstrated. The symptoms and signs of mediastinal emphysema are the result of "airblock." Pain may be mild or severe and may closely simulate coronary disease. Dyspnea and cyanosis are the result of increased mediastinal tension. Emphasis is placed on the importance of perialveolar and perivascular extension, as demonstrated by Macklin and Macklin, in evaluating dyspnea and cyanosis in cases of acute pulmonary infection, in asthmatics, in the newborn and in postoperative cases where trauma to pleura or extension of air from operative site to mediastinum seems unlikely. Early recognition of the real nature of the condition is imperative if prompt corrective measures are to be instituted. Posteroanterior roentgenograms may demonstrate one or both mediastinal pleural reflections or may reveal a globular radiolucency superimposed on the cardiac shadow. The lateral projection is the most revealing in outlining mediastinal collections of air in the majority of cases. Roentgen examination of the chest before tracheotomy is valuable for ruling out mediastinal emphysema as the cause of extreme dyspnea and cyanosis. Early roentgen diagnosis is important to prevent the development of so-called "malignant" pneumomediastinum, which may be fatal.

Aplasia of the Lung.—Ingram and co-workers report two cases of aplasia of the lung in which diagnoses were made during life in a girl aged 10 and in a male infant aged 14 months This brings to 18 cases the total number in which diagnoses have been made during life. The observations in the authors' first patient were further corroborated by angiocardiographic demonstration of a single pulmonary artery. This is believed to be the first time that such a study has been undertaken. The second patient had congenital hemivertebra of the thoracic portion of the spine, which occurrence had been previously reported. Aplasia of the lung is usually asymptomatic. It occurs more frequently in males than in females, in a ratio of three to two. It is seen three times as often on the left side as on the right. Diagnoses in these cases are usually the result of an accidental observation during physical examination or roentgenographic study in cases of extrapulmonary disease.

Management of the Depressed Patient.—Grahn points out that this is an age of unrest and that a large percentage of persons seeking medical aid are weighed down by vague depressions and anxieties. When a patient has, in addition, some actual physical illness, this uneasy, despondent attitude can seriously impede treatment and recovery. When no physical illness is present, the attitude is still a danger signal, a warning of a possibly much graver psychological upset in the future. The family physician, because of his familiarity with his patient's problems and background, has a good opportunity to help such persons. The ideal treatment would be to discover the causes of the patient's emotional turmoil and remove them, but since this is usually impossible, the author used medication. He treated 85 patients who had symptoms of depression or anxiety with a preparation combining *d*-amphetamine and amylethyl barbituric acid This combination has a tranquilizing effect that seems to neutralize extremes of mood, giving the patient a more normal outlook and behavior. Satisfactory results were secured in almost every case in which the symptoms were within "neurotic" limits; in active psychoses, the drug had little or no effect. The preparation is best used as a temporary measure, to alleviate depression or anxiety sufficiently for the patient to make an effort toward solving his problems or facing them in some more healthy manner. Although no drug can substitute for psychiatric treatment when that is indicated, the preparation described is extremely useful in relieving the relatively mild emotional symptoms seen constantly in general medical practice.

Treatment of Chronic Typhoid Carriers.—*Vichulis and his associates report the results of therapy in which suspensions of bacteria that produce an antibiotic against Salmonella typhi were fed to 25 chronic carriers. In addition, 62 chronic carriers were treated with penicillin, carinamide, sulfonamides and tetraiodophenolphthalein or alcohol. Smaller groups were treated with glucosulfone sodium (promin®) streptomycin, aureomycin, chloramphenicol, terramycin and two new chemotherapeutic agents. Of the 25 patients treated with aqueous suspensions of a typhoid-inhibiting, gram-positive, spore-forming bacillus resembling Bacillus subtilis, 19 were cured. All the six patients tested in whom this treatment failed were biliary carriers. Synergistic therapy, consisting of massive doses of penicillin in combination with carinamide, a mixture of three sulfonamides and tetraiodophenolphthalein, was effective in eight of 42 patients. A solution of penicillin, carinamide and sulfonamides in 5 per cent ethyl alcohol solution was given intravenously in conjunction with intramuscular and oral therapy to 17 patients. Failures resulted in 10 patients receiving less than five liters intravenously. Cure resulted in three, probable cure in another three and failure in one of seven patients receiving larger amounts. Treatment with glucosulfone sodium, streptomycin, aureomycin, chloramphenicol, terramycin and two chemotherapeutic agents was not too successful. Response to therapy was not correlated with age, sex, duration of the carrier state or occurrence of previous clinical typhoid fever. Bile cultures were of great importance in determining the likelihood of success with bacillus or synergistic therapy. When bile cultures are negative, bacillus therapy is indicated; when positive, synergistic drug therapy should be used. The authors also concluded that gallbladder visualization is a favorable prognostic observation with regard to medical therapy.

Syringe-Transmitted Jaundice Hepatitis.—Sherwood reports on syringe-transmitted hepatitis with jaundice in four diabetic patients. The icterogenic agent was transmitted by the multiple dose per syringe technic of administering insulin. The incubation period ranged from a minimum of 64 days to a maximum of 106 and is compatible with that of homologous serum jaundice. The course of the acute hepatitis with jaundice in these four patients was generally uneventful. There were no complications or deaths, and the diabetes was not difficult to control. All four recovered within a period of 13 to 46 days. The author concludes that the use of a fresh, sterile syringe and needle for any injection or blood collection will reduce the dissemination of infected serum from one patient to another. Until this is possible, sterilization of equipment by dry heat (160 C.) for a minimum of one hour is essential.

Streptomycin in Tuberculous Meningitis.—Brainerd and Eagle studied the effect of streptomycin on 27 patients with tuberculous meningitis. Both intrathecal and intramuscular routes of administration were used. The daily dose of streptomycin given by the intramuscular route varied from 12.9 to 130 mg. per kilogram of body weight, and the intrathecal dose from 0.4 to 9.3 mg. per kilogram. Toxic effects from the drug were frequent, although severe intoxication was uncommon. Nine patients died during the first four weeks of treatment without evidence of improvement; eight showed initial favorable response but later relapsed and died while still receiving treatment. Two patients showed initial favorable response but had slight persistent evidence of infection after completion of the five month therapeutic period; one patient was free of all evidence of central nervous system infection following the completion of five months' treatment, but meningitis recurred 100 days later; two were completely free of all evidence of meningeal infection at the completion of five months' treatment. These patients are completely well 16 and 17 months after the end of the therapeutic period. Five patients are still under observation. The age and sex of the patients influenced the outcome. The average age of the improved patients was 8.7 years, with a range of 9 months to 42 years. The average age of the unimproved group was 31.2 years, with a range of 8 months to 58 years. Eleven of 13 females responded favorably, whereas only seven of 14 males were improved. There was no correlation between the therapeutic result and the number of cells in the cerebrospinal fluid or the concentration of cerebrospinal fluid glucose, chloride or protein. The duration of the disease before treatment had no effect on the outcome. Most patients responding favorably to treatment received more than 60 mg. per kilogram daily of streptomycin intramuscularly and over 2.0 mg. per kilogram daily intrathecally. Toxic reactions to streptomycin are common with high dosage but are a justifiable risk. The authors emphasize the importance of prolonged follow-up of treated patients and conclude that the prognosis of tuberculous meningitis is still grave.

Sclerosing Lipogranuloma.—Smetana and Bernhard report 14 cases of subcutaneous sclerosing lipogranuloma characterized by tumorous swelling of subcutaneous fat in several locations. Nine men between the ages of 20 and 60 had lipogranulomatous lesions in the genital region. The duration from onset to operation varied from five weeks to eight years. The scrotum was involved in three instances, the penis in two, the scrotum and penis in two and the epididymis and the perineum in one case each. A history of physical trauma was recorded in three cases, and cutaneous lesions of an inflammatory nature were present in three others; there was no history of injury in the remaining three. Three men had lesions on the buttocks, one man had a lipogranuloma in the right arm and one in the orbit. The process persisted for a long time in most cases, and complete, spontaneous healing did not occur in any case, even after many years. Microscopic study of the lesions revealed definite disruption and alteration of the usual structure of the fat lobules of the subcutaneous adipose tissue. The normal fat cells were replaced by fat globules of varying size, sometimes smaller but often much larger than the original structure. Globules and masses of free fat became entrapped by the proliferating fixed tissue elements, forming connective tissue, which later matured into rather dense hyaline scar tissue. Sclerosing lipogranuloma is a reactive process that sometimes follows injury to subcutaneous fat tissue. The injury of the adipose tissue may be of varying character and probably sets off the reaction by interfering temporarily with the local blood supply and fat metabolism. Physical disruption and hemorrhage are not necessary to the development of this disease. The assumption that formation of fatty acids is essential in its genesis is probably erroneous. Spontaneous healing of lipogranuloma is extremely slow, since the only effective means of disposal of fats altered by injury are phagocytosis and transportation or the walling off and segregating of the affected from the unaffected area. Sclerosing lipogranuloma represents a specific reaction to an unspecific injury and follows a distinct course, which differs from that of the reaction following injury to other tissues. The only effective treatment known for sclerosing lipogranuloma is complete surgical removal of the involved tissues. "Traumatic" sclerosing lipogranuloma is related to, but may be distinguished from traumatic fat necrosis of the breast, relapsing nonsuppurative nodular panniculitis, adiponecrosis neonatorum, lipid pneumonia and pelvic lipogranuloma caused by iodized oils injected for uterosalpingography or other artificial lipogranulomas.

Pancreatic Lesions Associated with Colitis.—Ball and co-workers studied the pancreas in 86 consecutive cases of chronic ulcerative colitis in which necropsy was performed, and for comparison in an additional 86 cases in which necropsy was performed and chronic ulcerative colitis was not present. Interstitial pancreatitis was observed in 46 (53 per cent) of the 86 cases of active chronic ulcerative colitis. The interstitial pancreatitis was acute in two instances and chronic in 44 (severe in five, moderate in 17 and mild in 22). Only three instances of mild chronic interstitial pancreatitis were observed in the control group. In addition to the 46 case of interstitial pancreatitis, there were 11 cases in which definite pancreatic fibrosis and acinar atrophy were present. The pancreatic fibrosis probably represented the healed stage of chronic interstitial pancreatitis. Pancreatic acinar dilatation occurred in 46 cases (53 per cent). The incidence of these lesions was far in excess of those in the control group. The causative factors of these lesions could not be determined. The interstitial pancreatitis seen in the cases of colitis differed significantly from the clinicopathological entities of pancreatic necrosis and chronic relapsing pancreatitis. Fatty replacement of liver commonly accompanied pancreatic disease in the cases of colitis. There were no clinical signs of pancreatic disease in the course of ulcerative colitis, but future clinical and physiological research may elucidate the significance of these pathological observations.

*Use of Physostigmine in Treatment of Black Widow Spider Bite. O. R. Holloway.—p. 75.

Neostigmine and Atropine for Bite of Black Widow Spider.—Holloway discusses two patients who stated that they had been bitten by a black widow spider. Both were treated two hours after the bite occurred, and both had symptoms indicative of such a bite. They were treated with phyatromine,® which is a combination of physostigmine salicylate and atropine sulfate. The first patient was given a deep intragluteal injection of 1.5 cc. of phyatromine® plus ¼ grain (15 mg.) of morphine sulfate. Ten minutes later he began to relax, and five minutes later he was completely relaxed. The second patient was given only 2 cc. of phyatromine.® Here again relaxation of the muscular spasm occurred in about 15 minutes. Both patients recovered completely.

Homografts of Aorta.—Paolucci and Tosatti preserved pieces, 2 to 5 cm. in length, of abdominal aorta of dogs in pure alcohol at room temperature for five to 15 days. These segments were then transplanted into the abdominal aorta of five adult dogs between the renal and inferior mesenteric artery. The animals appeared in good condition fifteen days after the operation; they took nourishment and walked in an apparently normal manner. Roentgen examination was performed at intervals of one to nine months after the operation. There was no stenosis and no ectasia. Two dogs were killed seven and eight months after the operation. Union of the graft above and below the abdominal aorta was complete. The graft was covered by a connective tissue that made it adhere at one point to the surrounding tissues. The suture lines and the silk thread were clearly visible. There was no stenosis, thrombosis or bulging. The authors' method of preservation of homografts of aorta is simpler than that recently adopted by Gross and Peirce. Results obtained were satisfactory.

Esophagoduodenal Anastomosis.—Palumbo performed an esophagoduodenal anastomosis after a total gastrectomy in five men between the ages of 48 and 57. He prefers this anastomosis to esophagojejunostomy in certain selected cases in which the local pathological process and the proximity of a mobile duodenum are such that the cut end of the esophagus and the duodenum can be approximated without tension. The duodenum was mobilized by dissection in three of the cases of the second portion from its lateral peritoneal investment. This maneuver, with displacement of the duodenum and pancreas, did not compromise the blood supply or function of the structures. Death resulted from pulmonary edema in one patient on the sixth postoperative day. Necropsy showed definite and satisfactory healing at the site of the anastomosis. The postoperative course was complicated by a persistent draining sinus in two cases and by abscesses below and above the diaphragm in the two other cases. Barium studies showed the anastomosis to be intact and functioning without evidence of obstruction in all four cases. Esophagoduodenal anastomosis is simpler and easier to perform than esophagojejunostomy. It eliminates some of the steps required in the latter procedure, namely, closure of the duodenal stump and enteroanastomosis. Direct anastomosis of the esophagus with the duodenum appears to establish a more nearly normal anatomic and physiological continuity of the gastrointestinal tract.

Conservative Surgical Therapy in Brain Abscesses.—The conservative surgical method recommended by Mount for brain abscess consists of accurate localization of the abscess, with ventriculography if necessary. A trephine opening is made directly over the abscess; the dura is opened, and the exposed arachnoid and pia are cauterized, so as to seal the subarachnoid space and prevent meningitis. Then a needle is inserted for removal of pus for culture and smear. This is followed by insertion of a size 10 catheter with multiple openings at the end. The abscess cavity is carefully washed with penicillin until the return is clear and is then filled with penicillin. The catheter is sutured to the scalp and is brought out through the dressing in order to continue the irrigation and further instillation of the proper antibiotic as determined by the culture and smear of the pus. The abscess cavity is irrigated every six hours until the return is clear, and then penicillin is allowed to run into the cavity by gravity in order to completely fill it. Lumbar puncture is done if the antibiotic will not run in by gravity. The catheter is gradually withdrawn, 1 cm. every other day. This local treatment is combined with systemic antibiotic therapy administered either intramuscularly or orally. The author employed this method in 10 patients, two with cerebellar, one with subdural and the rest with cerebral abscesses. Recovery followed in eight patients. In 31 cases of brain abscess treated by other methods, the mortality rate was 45 per cent. The catheter method of treatment affords drainage of the abscess with a minimum of cerebral trauma, and it is therefore especially valuable when the abscess extends into important areas of the brain. If free exchange of fluid through the catheter cannot be obtained, the method is inadvisable.

Degenerative Changes in Pituitary Adenomas.—Brougham and his collaborators describe clinical and pathological observations on five patients with adenoma of the pituitary. The unique feature of these cases was a hemorrhage into the adenoma and/or extensive necrosis of the tumor, which was responsible for the sudden onset of a fairly uniform syndrome consisting of drowsiness, stupor or coma, headache and stiff neck, ocular palsies and sometimes amblyopia or hemiparesis. Some abnormality of the cerebrospinal fluid, usually the presence of blood or xanthochromia, sometimes only a slight pleocytosis or an elevated protein level, was invariably present. These acute retrogressive changes are believed to be related to the excessively rapid growth of some pituitary adenomas. The authors found only five verified cases in literature with similar symptomatology and pathological aspects but also two other cases in which the clinical aspects were highly suggestive of the same lesions. The authors stress the importance of a correct diagnosis. They list crises of adrenal insufficiency, a temporal lobe pressure cone and convulsive states as conditions that must be considered in the differential diagnosis. Although in some instances the apoplectic insult will prove swiftly fatal, supportive treatment is important in those patients who survive. One should watch for endocrinal deficiencies for which replacement therapy is possible. Some patients fail to rally, but others reach a plateau of partial improvement from which some of them may be rescued. Treatment should remain conservative as long as the clinical course is in the direction of recovery. Roentgen therapy is not advisable after pituitary apoplexy, because it might provoke additional acute degenerative changes. Few patients will have spontaneous improvement that is permanent. Extensive extravasation of blood at the infundibular region or a postinfarction swelling of the extrasellar portion of the adenoma would give rise, in most cases, either to paralytic effects on adjacent parts of the brain or to blockage of cerebrospinal fluid pathways and progressive internal hydrocephalus. Operation would then become necessary for relief of chronic headache, hemiparesis, impending stupor, papilledema or threatened optic atrophy. Surgical attack on an adenoma that has escaped from the confines of the sella is a formidable undertaking, but the results of intervention may be gratifying. Of three operations thus far reported as having been done for relief of apoplectic syndromes, two were highly successful.

Milk Factor in the Transmission of Mammary Carcinoma. J. Berner. —p. 375.

The "Milk Factor" in Carcinoma of the Breast.—The purpose of this study by Horne was to explore the possibility of the vertical transfer through breast feeding of an agent that might be a factor in the development of human mammary cancer. Case histories of well over 1,000 women with known carcinoma of the breast were made available by several hospitals. From these cases were chosen 88 patients whose mothers were still living. As a control group, a similar selection was made of 86 patients who had had vaginal plastic operations and in whom no neoplastic process had been discovered from the history, physical examination or pathological examination. The average age of the two groups was the same. Among the patients with cancer, nine (10.2 per cent) had never received any human milk. Among the patients who had had vaginal plastic operations, seven (8.1 per cent) had never received any human breast milk. Among the maternal family histories of the patients with cancer, exclusive of the patients' neoplasms, 87 tumors, of which 20 were cancers, were reported. Four of these cancers were in mothers of patients under study; one was of the breast, two of the intestines and one of the skin. Among the maternal family histories of the patients who had had vaginal plastic operations, 35 tumors, of which 14 were cancers, were reported. Only one of these cancers was in the mother of a patient under study; a cancer of the skin. The authors conclude from this that a woman may develop cancer of the breast without ever having received human breast milk. Whether the daughters of women with mammary cancer are more likely to develop the same disease if they are nursed has not been investigated and from the study here reported may not be inferred.

Tubed Pedicle Transplant in Reconstructions on Head and Neck.—Catlin points out that radical surgery for cancer of the head and neck will often produce large through and through defects involving the oral cavity or pharynx. Reconstruction of such defects can be satisfactorily accomplished by the tubed pedicle transplant. The tubed pedicle is usually elevated in one stage on the anterior chest wall. The skin defect beneath the tube is closed by primary suture. Occasionally the skin of the abdomen is used to form a tube. Since the commonest complication of head and neck cancer is metastasis to cervical lymph nodes, the author is opposed to use of the skin of the neck for the elevation of a pedicle. The reconstruction must be performed in stages and usually requires several months. A small recurrence can often be controlled by further surgery before the defect has been completely closed. The tubed pedicle offers the most flexible and useful epithelial lined transplant for the closure of through-and-through defects, even in the presence of tissue damaged by previous radiation therapy. When the defect is large, two or more tubes can be employed. They may be migrated together to the defect as quickly as a single tube. Adjustments and revisions of a tubed pedicle may be made repeatedly until the desired result is obtained. The pedicle is not always as cosmetically attractive as other reconstructions, but freedom from cancer and reasonably good function must be considered of greater importance than a good cosmetic result. The author describes the surgical principles of reconstruction with the tubed pedicle in three representative cases. Photographs and drawings accompany the descriptions.

Coxsackie and Poliomyelitis Viruses in Paralytic Poliomyelitis.—Melnick and Kaplan isolated both poliomyelitis virus and Coxsackie virus from the acute phase stools of paralytic patients during an epidemic of poliomyelitis. In two such cases, neutralizing antibody tests were made with acute and convalescent phase serum reacting with a suspension of virus obtained directly from acute phase stools. It was found that antibodies to Coxsackie and poliomyelitis viruses developed in both patients simultaneously. On the basis of the neutralization tests reported here and the finding of both viruses in the stools of 13 other patients in this epidemic, the authors believe that the failure to detect poliomyelitis virus in the stools of a paralytic patient excreting Coxsackie virus should be regarded as a technical difficulty and should not necessarily be regarded as an indication that Coxsackie virus caused the lesion resulting in paralysis. Until proved otherwise, the patient's paralytic manifestations should be considered to result from central nervous system infection with poliomyelitis virus. However, the finding of dual infections in poliomyelitis appears to occur too frequently to be regarded merely as coincidence. Is it possible that infection with poliomyelitis virus would have been a mild affair in these patients had not Coxsackie virus infection been superimposed? Consideration is being given to the possibility that Coxsackie virus infection may be one of the predisposing factors which may turn a nonparalytic into a paralytic case.

Aureomycin in Pernicious Anemia.—Lichtman and his associates gave aureomycin by mouth to four patients with Addisonian pernicious anemia in relapse and to one patient with nutritional macrocytic anemia. These patients showed a definite, although submaximal, hematological improvement. A fifth patient with Addisonian pernicious anemia was given aureomycin intravenously with no response. The mechanism of action of the aureomycin remains to be determined. Some possible explanations follow: 1. The sterilization of the gastrointestinal flora by aureomycin may remove a hemolytic toxin. 2. The lowering of the bacterial population in the gastrointestinal tract may increase the amount of dietary vitamin B_{12} available to the body (recent work has demonstrated that Escherichia coli has a decided affinity for vitamin B_{12} and can remove it from solution in vitro). 3. The lowering of the bacterial flora count by aureomycin may permit the growth of other micro-organisms, for example, yeasts, which in turn may produce pteroylglutamic acid or other hematopoietically active substances utilizable by the body.

Thoracic Aortic Coarctation: Its Experimental Production in Dogs, with Special Reference to Technical Methods Capable of Inducing Significant Intraluminal Stenosis. H. W. Clatworthy Jr., Y. Sako, T. C. Chisholm and others.—p. 245.
Functional Study of Afferent Fibers in Peripheral Sympathetic Nerves. L. W. Freeman, H. B. Shumacker Jr. and L. R. Radigan.—p. 274.
*Some Physiologic Effects of Lumbodorsal Sympathectomy for Hypertension. F. A. Simeone and O. Ramirez.—p. 282.
Venous Adaptation Following Bilateral Radical Neck Dissection with Excision of Jugular Veins. J. A. Gius and D. H. Grier.—p. 305.
Improved Method of Venography for Preoperative Evaluation of Postphlebitic Extremity. R. S. Martin and R. S. McCleery.—p. 322.
Surgical Treatment of Intracranial Angiomatous Malformations. C. Pilcher, W. F. Meacham and C. A. Cobb.—p. 342.
Complications Following Subtotal Gastric Resections Performed Since June, 1944, for Peptic Ulcer in 132 Patients: Comparison with Complications Following Vagotomy in 138 Patients. C. K. Lyons and K. S. Grimson.—p. 350.
New Surgical Treatment for Hirschsprung's Disease. O. Swenson. —p. 371.
Principle of Complete Exclusion in Fistulas of Small Intestine. S. P. Harbison.—p. 384.
Sickle-Cell Anemia: Surgical Problem: II. Further Observations on Surgical Implications of Sickle-Cell Anemia. R. H. Patterson, H. Wilson and L. W. Diggs.—p. 393.
Neck Dissections in Cancer of Lower Lip: Five-Year Results in 179 Patients. J. Modlin.—p. 404.
Permanent Camouflage of Corneal Scars Using Insoluble Tattoo Pigments. K. L. Pickrel, J. T. Metzger, J. Wilde and others.—p. 413.
Pheochromocytoma: Use of Adrenergic Blocking Agents in Operative Management. A. D. Console, H. S. Dunbar and B. S. Ray.—p. 428.

Quantitative Aspects of Hemorrhage.—Rudman and Stewart believe that the clinical tests usually employed to evaluate the severity of bleeding in acute hemorrhagic anemia do not always provide a clear picture. They report studies on 58 of 100 patients with bleeding peptic ulcer who were operated on immediately to control the hemorrhage. The results of the studies illustrate the severe degree of anemia and the critical nature of the hemorrhage in these patients. The hematocrit reading does not fall until the plasma volume begins to rise, that is, until new plasma protein enters the circulation, carrying fluid with it. Coincident with the peak value of plasma volume, the hematocrit reaches its lowest point. Thus, if patients are studied before maximal hemodilution occurs, there is a discrepancy between the total red cell mass and the hematocrit value. The red blood cell count, hemoglobin determination and hematocrit reading are all measures of red blood cell concentration, rather than of total circulating red blood cell mass. The former values will vary with changes in plasma volume. Not until all red blood cells lost in bleeding are replaced by an equivalent volume of plasma, will the hematocrit value, red blood cell count or hemoglobin fall to levels indicative of the true seriousness of the anemia. These tests cannot be relied on in the hours immediately following severe hemorrhage. The extent of bleeding may be grossly underestimated. Prior to the stage of maximum plasma hemodilution there is only one reliable index of severity of anemia, and that depends on a measurement of the total circulating red blood cell mass rather than on any study of red cell concentration. Since average transfusions of 2,320 cc. of blood were necessary to produce the 40 per cent increase in red blood cell mass, it may be calculated that an additional 1,450 cc. would be required to bring about restoration of a normal red blood cell mass. This total of 3,770 cc. of blood is equivalent to 60 per cent of the normal blood volume and indicates the large quantities of blood needed for adequate replacement. Patients can survive large and rapid blood losses even in the presence of cardiopulmonary disease and old age. Rapid transfusion of large quantities of whole blood can be safely carried out in these cases.
